Welcome and introduction

On behalf of the optimal care pathways team, welcome to the second edition of the optimal care pathway guides to better cancer care.

Some cancers are simple to treat; many are complex. But the principles of high-quality care are similar for all cancers and, if followed, are likely to achieve the best outcomes for patients and their families and carers.

Australia has an excellent healthcare system, but the pathway for cancer patients can be complex. Often multiple health professionals are involved and both public and private types of health care are used. Our cancer survival rates are as good as anywhere in the world, but many patients still report difficulties during their care and, importantly, outcomes among different groups vary across the country.

That's why we have developed the optimal care pathways. The optimal care pathways describe an integrated model of cancer care that puts the patient's needs first, along with the best of technical care. They provide a national standard for the high-quality cancer care that all Australians should expect. We all believe when it comes to cancer care, our patients and their families deserve the best care available.

The optimal care pathways should be read and understood by all those involved in cancer care. This includes all health professionals, from surgeons, oncologists, haematologists, radiologists, general practitioners and other doctors to allied health professionals, nurses and managers of cancer services. Trainees in all disciplines should absorb the messages contained in the optimal care pathways.

We also recommend the optimal care pathways to all people affected by cancer, both patients and carers. We encourage you to use the optimal care pathways to guide discussions with your healthcare team and to help you make informed decisions about what's right for you. There is a specific optimal care pathway for Aboriginal and Torres Strait Islander people, while the *Guides to best cancer care* for consumers are available in eight languages.

The optimal care pathways are endorsed by Cancer Australia, the former National Cancer Expert Reference Group (a committee that reported to the former Australian Health Ministers Advisory Committee and, through this committee, to the former Council of Australian Governments Health Council) and all states and territories. The optimal care pathways have Australia-wide acceptance and government support.

It's important to note that the optimal care pathways are cancer pathways, not clinical practice guidelines. The decision about 'what' treatment is given is a professional responsibility and will usually be based on current evidence, clinical practice guidelines and the patients' preferences.

The optimal care pathways were updated in 2020, at a time when the global COVID-19 pandemic was challenging the Australian healthcare sector in an unprecedented way. The pandemic led to rapid practice change, including greater uptake of telehealth. Where appropriate, learnings have informed the review of the pathways.

I would like to thank everyone involved for their generous contribution to the development and revision of the optimal care pathways. This includes many health professionals (noted in the optimal care pathways) and the strong support of federal and state governments.

Professor Robert J S Thomas OAM

Chair, Optimal Care Pathways Project Steering Committee

Summary

Support: Assess supportive care needs at every step of the pathway and refer to appropriate health professionals or organisations.

The optimal care pathways describe the standard of care that should be available to all cancer patients treated in Australia. The pathways support patients and carers, health systems, health professionals and services, and encourage consistent optimal treatment and supportive care at each stage of a patient's journey. Seven key principles underpin the guidance provided in the pathways: patient-centred care; safe and quality care; multidisciplinary care; supportive care; care coordination; communication; and research and clinical trials.

This quick reference guide provides a summary of the *Optimal care pathway for people with breast cancer*.

Please note that not all patients will follow every step of the pathway.

Step 1: Prevention and early detection

Risk factors

See the **optimal care pathway for people with breast cancer** for a comprehensive list of risk factors for developing breast cancer.

Prevention

Recommendations that may assist in preventing breast cancer include the following:

- Maintain a healthy weight.
- Avoid or limit alcohol intake.
- Get regular exercise.
- Avoid or limit use of hormone replacement therapy.
- Consider additional prevention strategies in people with increased risk (e.g. gene mutation carriers).

Individual risk assessment will help guide additional prevention strategies.

Risk reduction

For women with an increased risk of breast cancer, anti-hormonal risk-reducing medication lowers risk. Women at very high risk may consider risk-reducing surgery.

Risk assessment tools

Assessing a patient's personal breast cancer risk will help guide appropriate strategies.

Validated computerised breast cancer risk assessment tools that estimate a woman's breast cancer risk include:

- iPrevent <<https://www.petermac.org/iprevent>>
- IBIS tool <<https://ibis.ikonopedia.com>>
- CanRisk Web Tool <<https://canrisk.org/>>.

Screening recommendations

- Breast awareness
- BreastScreen Australia offers 2-yearly mammographic screening targeted at asymptomatic women aged 50–74 (although women over age 40 can attend on request).
- A doctor's referral is not required for this screening, but a GPs' encouragement is a key factor in participation.

Women invited to screening must be informed of the risks and benefits of mammographic screening.

Checklist

- Individual risk of developing cancer assessed and familial cancer service referral considered
- Asymptomatic women aged 50–74 years encouraged to participate in the BreastScreen Australia program
- Recent weight changes discussed and patient's weight recorded
- Alcohol intake discussed and recorded and support for reducing alcohol consumption offered if appropriate
- Smoking status discussed and recorded and brief smoking cessation advice offered to smokers
- Physical activity recorded
- Referral to a dietitian, physiotherapist or exercise physiologist considered
- Education on being sun smart considered

Step 2: Presentation, initial investigation and referral

The following signs and symptoms should be investigated:

- a persistent new lump or lumpiness, especially involving only one breast
- a change in the size or shape of a breast
- a change to a nipple, such as crusting, ulceration, redness or inversion
- a nipple discharge that occurs without manual expression
- a change in the skin of a breast, such as redness, thickening or dimpling
- axillary mass(es)
- an unusual breast pain that does not go away.

Checklist

- Signs and symptoms recorded
- Supportive care needs assessment completed and recorded, and referrals to allied health services actioned as required
- Patient notified of support services such as Cancer Council 13 11 20

Step 2: Presentation, initial investigations and referral continued

Initial investigations include a triple test of the three diagnostic components:

- medical history and clinical breast examination
- imaging – mammography and/or ultrasound
- non-excision biopsy – preferably a core biopsy.

Referral options

At the referral stage, the patient's GP or other referring doctor should advise the patient about their options for referral, waiting periods, expertise, if there are likely to be out-of-pocket costs and the range of services available. This will enable patients to make an informed choice of specialist and health service.

Communication

The GP's responsibilities include:

- explaining to the patient and/or carer who they are being referred to and why
- supporting the patient and/or carer while waiting for specialist appointments
- informing the patient and/or carer that they can contact Cancer Council on 13 11 20.

Checklist

- Referral options discussed with the patient and/or carer including cost implications

Timeframe

A patient with signs and symptoms that may suggest breast cancer should see a GP **within 2 weeks**.

Optimally, tests should be done **within 2 weeks**.

A positive result on any component of the triple test warrants specialist surgical referral. Ideally, the surgeon should see the patient with proven or suspected cancer **within 2 weeks** of diagnosis. If necessary, prior discussion should facilitate referral.

Step 3: Diagnosis, staging and treatment planning

Diagnosis

The following investigations should be undertaken:

- breast imaging tests including bilateral mammography and ultrasound (or MRI in selected cases)
- ultrasound of the axilla (including fine-needle aspiration of nodes if the axillary ultrasound is abnormal)
- breast core biopsy, if not already undertaken, which allows breast cancer receptor profiles (ER, PR, HER2) to be determined.

Staging investigations for distant disease

Staging is appropriate for patients with confirmed locally advanced or nodal disease and for any patient with clinical symptoms or clinical suspicion of metastatic disease.

Germline genetic testing

For detailed information and referral guidelines for breast cancer risk assessment and consideration of genetic testing, read *eviQ's Referral guidelines for breast cancer risk assessment and consideration of genetic testing* <<https://www.eviq.org.au/cancer-genetics/adult/referral-guidelines/1620-referral-guidelines-for-breast-cancer-risk-as>>.

Treatment planning

Ideally, the multidisciplinary team should discuss all newly diagnosed patients

with breast cancer **before** surgery or neoadjuvant chemotherapy.

Refer to a breast cancer nurse **within 7 days** of a definitive diagnosis.

Research and clinical trials

Consider enrolment where available and appropriate. Search for a trial <www.australiancancertrials.gov.au>.

Communication

The lead clinician's¹ responsibilities include:

- discussing a timeframe for diagnosis and treatment options with the patient and/or carer
- explaining the role of the multidisciplinary team in treatment planning and ongoing care
- encouraging discussion about the diagnosis, prognosis, advance care planning and palliative care while clarifying the patient's wishes, needs, beliefs and expectations, and their ability to comprehend the communication
- providing appropriate information and referral to support services as required
- communicating with the patient's GP about the diagnosis, treatment plan and recommendations from multidisciplinary meetings (MDMs).

Checklist

- Diagnosis confirmed
- Referral to a familial cancer service considered
- Performance status and comorbidities measured and recorded
- Patient discussed at an MDM and decisions provided to the patient and/or carer
- Clinical trial enrolment considered
- Supportive care needs assessment completed and recorded and referrals to allied health services actioned as required
- Patient referred to support services (such as Cancer Council) as required
- Treatment costs discussed with the patient and/or carer

Timeframe

Diagnostic investigations should be completed **within 2 weeks** of the initial specialist consultation.

¹ Lead clinician – the clinician who is responsible for managing patient care.

The lead clinician may change over time depending on the stage of the care pathway and where care is being provided.

Step 4: Treatment

The aim of treatment for breast cancer and the types of treatment recommended depend on the type, stage and location of the cancer and the patient's age, health and preferences.

Establish intent of treatment

- Curative
- Anti-cancer therapy to improve quality of life and/or longevity without expectation of cure
- Symptom palliation

Surgery for early breast cancer includes:

- breast-conserving surgery or mastectomy
- sentinel node biopsy +/-/or axillary dissection
- oncoplastic surgery
- reconstruction immediately after a mastectomy or delayed to an appropriate time.

Neoadjuvant therapy, usually

chemotherapy may be appropriate for patients with:

- triple-negative or HER2-positive cancer
- locally advanced or inflammatory breast cancer
- large operable cancers, with the aim of reducing the tumour size.

All patients with:

- invasive cancer should be considered for **systemic therapy**
- hormone receptor-positive cancer should be considered for **endocrine therapy**.

Adjuvant bisphosphonates improve survival and should be considered for selected patients being treated for breast cancer with curative intent.

Radiation therapy may be beneficial for:

- patients with early breast cancer after breast-conserving surgery
- selected patients after a mastectomy.

Partial breast irradiation can be considered for selected patients with early breast cancer.

Communication

The lead clinician and team's responsibilities include:

- discussing treatment options with the patient and/or carer including the intent of treatment as well as risks and benefits
- discussing advance care planning with the patient and/or carer where appropriate
- communicating the treatment plan to the patient's GP
- helping patients to find appropriate support for exercise programs where appropriate to improve treatment outcomes.

Checklist

- Intent of treatment established
- Patient made aware that reconstructive surgery can be immediate or delayed
- Risks and benefits of treatments discussed with the patient and/or carer
- Treatment plan discussed with the patient and/or carer
- Treatment plan provided to the patient's GP
- Treating specialist has adequate qualifications, experience and expertise
- Supportive care needs assessment completed and recorded, and referrals to allied health services actioned as required
- Advance care planning discussed with the patient and/or carer

Timeframe

Surgery should ideally occur within **5 weeks** of the decision to treat (for invasive breast cancer) or **4–6 weeks** after neoadjuvant systemic treatments are complete.

Neoadjuvant chemotherapy should begin **within 4 weeks** of the decision to treat.

Adjuvant chemotherapy should begin **within 6 weeks** of surgery.

Adjuvant chemotherapy for triple-negative breast and HER2-positive breast cancer should begin **within 4 weeks** of surgery.

Endocrine therapy should begin **as soon as appropriate** after chemotherapy, radiation therapy and/or surgery is complete (and in some cases will be started during neoadjuvant treatment).

Radiation therapy should begin **3–4 weeks** after chemotherapy, or **within 8 weeks** of surgery, for patients who do not have adjuvant chemotherapy.

Step 5: Care after initial treatment and recovery

Provide a treatment and follow-up summary to the patient, carer and GP outlining:

- the diagnosis, including tests performed and results
- tumour characteristics
- treatment received (types and date)
- current toxicities (severity, management and expected outcomes)
- interventions and treatment plans from other health professionals
- potential long-term and late effects of treatment and care of these
- supportive care services provided
- a follow-up schedule, including tests required and timing

- contact information for key healthcare providers who can offer support for lifestyle modification
- a process for rapid re-entry to medical services for suspected recurrence.

Communication

The lead clinician's responsibilities include:

- explaining the treatment summary and follow-up care plan to the patient and/or carer
- informing the patient and/or carer about secondary prevention and healthy living
- discussing the follow-up care plan with the patient's GP.

Checklist

- Treatment and follow-up summary provided to the patient and/or carer and the patient's GP
- Supportive care needs assessment completed and recorded and referrals to allied health services actioned as required
- Patient-reported outcome measures recorded

Step 6: Managing recurrent, residual or metastatic disease

Detection

Most locally recurrent or metastatic will be detected via routine follow-up or by the patient presenting with symptoms.

Treatment

Evaluate each patient for whether referral to the original multidisciplinary team is appropriate. Treatment will depend on the location and extent of disease, previous management and the patient's preferences.

Refer to the 5th ESO-ESMO International Consensus Guidelines for Advanced Breast Cancer (ABC 5) <<https://www.esmo.org/guidelines/breast-cancer/consensus-recommendations-advanced-breast-cancer-abc-5>>.

Advance care planning

Advance care planning is important for all patients but especially those with

advanced disease. It allows them to plan for their future health and personal care by thinking about their values and preferences. This can guide future treatment if the patient is unable to speak for themselves.

Survivorship and palliative care

Survivorship and palliative care should be addressed and offered early. Early referral to palliative care can improve quality of life and in some cases survival. Referral should be based on need, not prognosis.

Communication

The lead clinician and team's responsibilities include:

- explaining the treatment intent, likely outcomes and side effects to the patient and/or carer and the patient's GP.

Checklist

- Treatment intent, likely outcomes and side effects explained to the patient and/or carer and the patient's GP
- Supportive care needs assessment completed and recorded and referrals to allied health services actioned as required
- Advance care planning discussed with the patient and/or carer
- Patient referred to palliative care if appropriate
- Routine follow-up visits scheduled

Step 7: End-of-life care

Palliative care

Consider a referral to palliative care. Ensure an advance care directive is in place.

Communication

The lead clinician's responsibilities include:

- being open about the prognosis and discussing palliative care options with the patient and carers if appropriate
- establishing transition plans to ensure the patient's needs and goals are considered in the appropriate environment.

Checklist

- Supportive care needs assessment completed and recorded, and referrals to allied health services actioned as required
- Patient referred to palliative care
- Advance care directive in place

Visit our guides to best cancer care webpage <www.cancercareguides.org.au> for consumer guides. Visit our OCP webpage <www.cancer.org.au/OCP> for the optimal care pathway and instructions on how to import these guides into your GP software.

Intent of the optimal care pathways

Optimal care pathways map seven key steps in cancer care. Each of these steps outlines nationally agreed best practice for the best level of care. While the seven steps appear in a linear model, in practice, patient care does not always occur in this way but depends on the particular situation (e.g. the type of cancer, when and how the cancer is diagnosed, prognosis, management, the patient's decisions and their physiological response to treatment).

The principles underpinning optimal care pathways always put patients at the centre of care throughout their experience and prompt the healthcare system to deliver coordinated care.

The optimal care pathways do not constitute medical advice or replace clinical judgement, and they refer to clinical guidelines and other resources where appropriate.

Figure 1: The optimal care pathway

Optimal care pathway resources

There are three resources for each pathway: an optimal care pathway, a quick reference guide for health professionals and a guide to best cancer care for patients, carers and families.

Optimal care pathways

This optimal care pathway is designed for **health professionals and health services**. However, **patients and carers** may find useful information in this version to help understand the processes their treating health professionals are following.

This resource aims to:

- assist health professionals to provide optimal care and support to patients with cancer, their families and carers
- provide optimal timeframes for delivering evidence-based care
- emphasise the importance of communication and collaboration between health providers and people affected by cancer
- assist and inform new health professionals or trainees who are entering the cancer care workforce
- provide value to health systems to identify gaps in current cancer services, bring about quality improvement initiatives and improve how services are planned and coordinated. Adherence to the pathways should be measured wherever possible.

Visit the Cancer Council website <www.cancer.org.au/OCP> to view the optimal care pathways.

Quick reference guides

The quick reference guides are for **health professionals and health services**. They provide a summary of each optimal care pathway for health professionals and patients.

The quick reference guides include:

- optimal timeframes within which tests or procedures should be completed
- checklists with indicators related to recommendations in the optimal care pathway.

Visit the Cancer Council website <www.cancer.org.au/OCP> to view the quick reference guide for this optimal care pathway.

Guides to best cancer care

The guides to best cancer care are **consumer** resources that help patients understand the optimal cancer care that should be provided at each step. Carers, family and friends may also find the guides helpful.

The guides to best cancer care:

- include optimal timeframes within which tests or procedures should be completed
- include prompt questions to support patients to understand what might happen at each step of their cancer journey and to consider what questions to ask
- provide information to help patients and carers communicate with health professionals
- are available in eight languages.

Visit the Cancer Council's website <www.cancercareguides.org.au> to view the guides to best cancer care.

Optimal care pathway for Aboriginal and Torres Strait Islander people with cancer

The *Optimal care pathway for Aboriginal and Torres Strait Islander people with cancer* provides a tool to help reduce disparities and improve outcomes and experiences for Aboriginal and Torres Strait Islander people with cancer. This resource can be used in conjunction with the optimal care pathway for each cancer type.

Visit the Cancer Australia website <<https://www.canceraustralia.gov.au/affected-cancer/atsi/resources-health>> to view the optimal care pathway for Aboriginal and Torres Strait Islander people.

Principles of the optimal care pathway

The seven principles of care define appropriate and supportive cancer care that is the right of all patients and the right of those caring for and connected with them.

Figure 2: The seven principles underpinning the optimal care pathway

Principle 1: Patient-centred care

Patient-centred care informs and involves patients in their care and respects and responds to the preferences, needs and values of patients, families and carers.

A patient-centred focus increases the experience and satisfaction of patients, their families and carers, and staff, as well as safety and cost-effectiveness (ACSQHC 2019a).

Patient-centred care means:

- patients are informed and involved in decisions about their cancer and the treatment, post-treatment and recovery program ahead
- patients, their families and carers are provided with access to appropriate and accessible health information
- respect for the cultural and religious beliefs of patients and their families is demonstrated when discussing the diagnosis of cancer
- active communication is used to engage patients, their families and carers in the care process – an essential step for patients to be informed
- care processes are mutually beneficial for patients and providers
- special needs are addressed – for example, the needs of people with disabilities or mental health issues.

Informed choice and consent

An informed patient has greater confidence and competence to manage their cancer journey.

Health professionals are responsible for enabling patients to make informed choices according to their preferences, needs and values. Patients should be provided with:

- individualised and timely information and guidance about their treatment
- details of their care, including the advantages and disadvantages of each treatment, the associated potential side effects, the likely outcomes on their performance status (how well a patient is able to carry out activities of daily life) and subsequently their quality of life and any financial implications, at each stage of the pathway (ACSQHC 2020).

Health professionals have a legal responsibility to obtain consent for all procedures from either the patient or their substitute decision-maker if they are not deemed competent.

Referral choices and informed financial consent

Patients have the right to receive the information they need to be able to make an informed decision on where to be referred for treatment. Treating specialists and practitioners should clearly explain the costs or how to find out the costs of services, tests and treatment options upfront to avoid consumers experiencing 'bill shock'.

At the time of referral, the patient's general practitioner or other referring doctor should discuss the different options for referral, waiting periods, expertise, if there are likely to be out-of-pocket costs and the range of services available. This will enable patients to make an informed choice of specialist and health service. Referral decisions influence the care patients receive along the pathway and the direct and indirect costs they and their carers may incur. Different referrals have different costs:

- referral to a public hospital, which may involve some costs
- initial referral to a private specialist with associated costs, with the option of ongoing treatment in a public hospital at any time
- referral to a patient's choice of practitioner for immediate and ongoing private hospital management with associated costs.

Patients should be made aware that even though public hospital health care is 'free' to all Australian citizens and most permanent residents of Australia, there are still associated direct costs such as:

- over-the-counter medication and prescriptions
- wound dressings
- travel costs
- parking fees
- tests that are not covered by Medicare.

A cancer diagnosis and treatment may affect a patient's or carer's income. This is an indirect cost associated with cancer. Social work support is essential to help patients and their families deal with this issue. Patients should be advised not to undergo private care with significant out-of-pocket expenses if financially constrained. Specialists in private practice need to explain costs at the start of each new treatment to acknowledge the cumulative out-of-pocket expenses that patients can incur.

For more information on informed financial consent see Cancer Council's 'Standard for informed financial consent' <<https://www.cancer.org.au/health-professionals/resources/informed-financial-consent>>.

Financial counselling services can provide advice on dealing with financial difficulties. These services can be accessed publicly (via social workers at hospitals, financial counsellors at neighbourhood houses or rural financial aid), privately or through cancer support services such as local charity groups or social work services.

For practical and financial assistance, patients may consider Cancer Council's financial services <<https://www.cancer.org.au/about-cancer/patient-support/practical-and-financial-assistance.html>>.

Shared care

Shared care between a cancer specialist and primary care health professional is delivered in two or more settings by two or more professionals. The primary care provider is usually a general practitioner but can include nurses and allied health practitioners. Shared care can be delivered throughout the care pathway including during treatment, follow-up care, survivorship care and end-of-life care.

Shared care offers several advantages to patients, including the potential for treatment closer to home and more efficient care with less duplication and greater coordination. Evidence comparing shared care and specialised care indicates equivalence in outcomes including recurrence rate, cancer survival and quality of life (Cancer Research in Primary Care 2016).

Telehealth can enable efficient shared care and should be explored for all patients. Patients in some rural or remote locations may access specialists via Medicare Benefit Scheme funded telehealth consultations. General practitioners working in rural or remote locations should be aware of specialist multidisciplinary teams with facilities to reduce the travel burden and costs for patients.

Principle 2: Safe and quality care

Hospitals and health professionals are responsible for providing safe and quality care.

Health professionals need to have appropriate training and experience to undertake treatment for breast cancer. Patients should be referred to an individual practitioner or service with appropriate expertise.

Safe and high-quality care is care provided by appropriately trained and credentialed health professionals who undertake regular quality reviews of their performance, contribute to regular audits of their care and are actively involved in continuing professional development. Hospitals and clinics must have the equipment, staff numbers, policies and procedures in place to support safe and high-quality care for cancer patients. Patients should be offered the safest options for care, which may include using telehealth (Cancer Australia 2020a).

Hospital quality committees should ensure all health care is informed by evidence, and health professionals and health service managers (including executives) have a responsibility to evaluate and monitor their practice. Optimal care pathways provide a framework to help evaluate and monitor practice over time. Services should be routinely collecting relevant minimum datasets to support benchmarking, quality care and service improvement. Hospital committees and health professional peak bodies should be auditing this process (ACSQHC 2017, 2020).

The Australian Council on Health Standards <<https://www.achs.org.au/>> has created a set of indicators that helps hospitals conform to appropriate standards.

Patient-reported experience and outcome measures

Patient-reported experience measures (PREMs) and patient-reported outcome measures (PROMs) should be incorporated into routine cancer care.

PREMs are used to obtain patients' views and observations on aspects of healthcare services they have received (AIHW 2018a). Patient experience data is collected for specific services and then relayed to service providers to instigate improvements in patient services (ACSQHC 2019b).

The Australian Hospital Patient Experience Question Set (AHPEQS) is a tool used to assess patient experiences of treatment and care in a private or public hospital. AHPEQS helps to improve the safety and quality of health care by allowing organisations to understand the patient's perspective (AIHW2018a; ACSQHC 2019b).

PROMs measure aspects of a person's health status such as symptoms, quality of life and needs and are collected directly from patients either online, via a smartphone or through paper-based means.

Collecting PROMs, and then instigating an appropriate clinical response, has been shown to prolong survival, reduce health system use and improve patients' quality of life. While there are many sets of PROMs questions that are relevant to any cancer patient, specific questions can be tailored to particular cancer types, populations or different phases of cancer care.

Principle 3: Multidisciplinary care

Multidisciplinary care is an integrated team approach that involves all relevant health professionals discussing all relevant treatment options and making joint recommendations about treatment and supportive care plans, taking into account the personal preferences of patients.

Multidisciplinary care improves patient outcomes. Cancer Australia's 'Principles of multidisciplinary care' provides a flexible definition, allowing services to vary implementation according to cancer type and the service location. The principles stipulate:

- a team approach that involves core disciplines that are integral to providing good care, including general practice, with input from other specialties as required
- communication among team members about treatment planning and plans for follow-up
- access to the full therapeutic range for all patients, regardless of geographical remoteness or size of institution
- care delivery in accordance with nationally agreed standards
- patient involvement in decisions about their care (Cancer Australia 2019a).

In addition to these principles, treatment teams should consider clinical trial participation for all eligible patients.

Multidisciplinary meetings, often called MDMs, should be based on the principles outlined above.

For more information on the principles of multidisciplinary care and the benefits of adopting a multidisciplinary approach, see Cancer Australia's 'Principles of multidisciplinary care' <www.canceraustralia.gov.au/clinical-best-practice/multidisciplinary-care/all-about-multidisciplinary-care/principles-multidisciplinary-care>.

Principle 4: Supportive care

Supportive care is a vital part of any cancer treatment program. Supportive care deals with issues that emerge for patients, families and carers from the effects of the cancer diagnosis and its treatment. It is made up of all the services, information and resources patients may need to meet their physical, psychological, social, information and spiritual needs from the time of diagnosis.

Supportive care may be 'patient-defined' and based on unmet needs. It is a core component of evidence-based clinical care and its benefits are well established. All cancer patients and their carers should be formally supported and have access to understandable, relevant information about the medical, practical and emotional aspects of the cancer and its treatment (Fitch 2008). The wishes and needs of the patient, their family and their carers should determine the level of support provided. Supportive care is a standard or routine aspect of cancer care and the treatment team should make patients aware of this.

Supportive care should begin from the time of diagnosis and continue throughout the cancer pathway.

For health professionals, supportive care involves:

- screening and assessing patients and families for their supportive care needs
- providing patients with access to a range of multidisciplinary support services, groups and therapies designed to assist them to live with cancer and its treatment and optimise recovery
- optimising referral pathways to community support organisations (cancer-related non-government, not-for-profit and charities) that provide services to cancer survivors – these address many of the care-navigation, psychosocial and information needs of cancer survivors and those affected by cancer (Australian Cancer Survivorship Centre 2019)
- being aware of and delivering culturally appropriate care.

All members of the multidisciplinary team have a role in providing supportive care along the care pathway, with special attention at transition points.

Supportive care involves routinely and systematically assessing patients to determine their needs. Health professionals can use a variety of validated screening tools for this task (see box on page 13). Clinical review and individual assessment are still required to ensure all patient concerns are identified.

More information

Visit the WeCan website <www.wecan.org.au> for information and resources on supportive care.

Validated screening tools

- National Comprehensive Cancer Network Distress Thermometer and Problem Checklist
- Supportive Care Needs Assessment Tool for Indigenous People (SCNAT-IP).

Key review points

The treatment team should assess patients for supportive care needs at these key stages:

- initial presentation or diagnosis (first three months)
- the beginning of treatment or a new phase of treatment
- change in prognosis
- if a patient is found to have a germline genetic mutation predisposing to cancer
- end of treatment
- throughout survivorship
- diagnosis of recurrence
- change in or development of new symptoms
- palliative care
- end-of-life care
- other time points based on clinical judgement.

The team also needs to decide whether the patient requires ongoing referral to supportive care services. Access to services can be through general practice–led chronic disease management plans, team care arrangements and mental health plans. Community support services also have a role to play.

See Appendices A, B and C for more information on supportive care and the specific needs of people that may arise.

Principle 5: Care coordination

Care coordination is the responsibility of every professional, both clinical and non-clinical, who works with patients, their families and carers.

Seamless care coordination is essential for patients to successfully navigate the complex health system. Care coordination is a comprehensive approach to achieving continuity of care for patients. It aims to ensure care is delivered in a systematic, connected and timely way that promotes efficiency and reduces the risk of duplication and over-servicing to meet the medical and personal needs of patients.

Care coordination includes:

- proactive and timely communication with patients, their families and carers
- treatment plans, survivorship care plans and/or advance care directives
- coordinated appointments to ensure timely diagnosis, treatment and survivorship care
- appropriate tests and results being available to the treating team so treatment decisions can be made
- medical records being available to all members of the treating team and at scheduled appointments
- translation or interpreter services arranged if the patient/carer is from a non-English-speaking background or has difficulty communicating due to a physical disability
- practical support such as transport, accommodation, advance care planning and financial support
- referral and access to supportive care
- access to clinical trials
- access to telehealth for people in rural and remote areas and for managing vulnerable patients.

Care coordination brings together different health professionals, teams and health services. It also encompasses MDMs, multidisciplinary assessment clinics, supportive care screening and assessment, referral practices, data collection, common protocols, information for patients and individual clinical treatment.

Care coordination should cross the acute and primary care interface and should aim to achieve consistency of care through clear communication, linkages and collaborative integrated care planning.

Care coordination can be facilitated through electronic health record management such as My Health Record. My Health Record is a secure online database that helps with data collection and care coordination (My Health Record 2019).

Formal care coordination through appointed care coordinators plays an important role in managing and supporting patients through the health system. The availability of dedicated care coordinators varies across states and territories according to the complexity of care required and local service capacity and resourcing.

Principle 6: Communication

Everyone employed in the healthcare system is responsible for ensuring the communication needs of patients, their families and carers are met.

Good and open communication is a key principle of care for cancer patients. This includes communication between oncology and primary care health professionals and with patients. General practitioners should be involved in care from the point of diagnosis, and patients should be encouraged to maintain a relationship with their general practitioner through all stages of cancer care. Communication should be regular and timely.

Attendance of a family member or carer at clinical appointments is beneficial for many patients, as the family member or carer can provide informational and emotional support. General practitioners and clinicians should encourage and support the involvement of family members and carers by providing an inclusive and supportive consultation environment (Laidsaar-Powell et al. 2018a). Laidsaar-Powell et al. provide evidence-based guidance on how to support family member or carer involvement in consultations (Laidsaar-Powell et al. 2018a, 2018b).

Every person with cancer will have different communication needs, including cultural and language differences. When anyone involved in treatment communicates with patients, they should be truthful and transparent but aware of cultural and psychological sensitivities. In communicating with patients, healthcare providers should undertake to:

- empower patients to be active in treatment discussions
- use professionally trained interpreters if required – for example, when communicating with people from culturally diverse backgrounds whose primary spoken language is not English and for people with a hearing impairment (visit the Translating and Interpreting Services website <www.tisnational.gov.au> for more information on interpreter and language services)
- use culturally sensitive and appropriate forums of communication for people from culturally diverse backgrounds and Aboriginal and Torres Strait Islander people, as appropriate
- provide appropriate information for people from culturally diverse backgrounds
- provide information on community-based supportive care services and resources to patients and their families and carer
- identify the patient's substitute treatment decision-maker to ensure they are involved in relevant discussions
- ensure patients, their families or their carers have the opportunity to ask questions
- seek consent before conveying information between health professionals or healthcare teams or with family and carers
- be respectful if a patient seeks a second opinion from another health professional
- ensure patients do not have to convey information between areas of care (it is the provider's and healthcare system's responsibility to transfer information between areas of care)
- communicate in plain language (avoiding complex medical terms and jargon)
- ensure information is communicated at a level relevant to the patient's health literacy and that of their families and carers (ACSQHC 2020)
- use tools, diagrams and aids as appropriate (Gilligan et al. 2017)
- ensure the patient is aware of how to access electronic patient information, where appropriate

- allow enough time for communication, especially when conveying complex or sensitive information such as an initial diagnosis
- check the patient's and/or their family or carer's understanding by asking the patient and/or their family or carer to say in their own words what has been conveyed.

Healthcare providers should also consider offering patients a question prompt list before a consultation and recordings or written summaries of their consultations afterwards. Question prompt lists are effective in improving communication and the psychological and cognitive outcomes of cancer patients. Recordings or summaries of key consultations improve patients' recall of information and satisfaction (Hack et al. 2012). Written care plans, treatment summaries, survivorship care plans and advance care directives are effective records and communication tools.

Communication skills training programs that use role-play to develop skills and observe patient interactions to provide feedback, should be available to health professionals at every level of practice (Gilligan et al. 2017).

Communication skills training programs and resources can be found on the following websites:

- Australian Commission on Safety and Quality in Healthcare, Communicating for safety resource portal <<https://c4sportal.safetyandquality.gov.au>>
- state and territory Cancer Councils <www.cancer.org.au/about-us/state-and-territory-councils/> for the relevant council
- eviQ <<https://education.eviq.org.au>>
- VITAL talk <www.vitaltalk.org>.

Telehealth has become an increasingly acceptable alternative to face-to-face consultations.

When using telehealth, the team must consider what is best for the patient, including the patient's preferences of the patient. A face-to-face consultation should be the first option, if it is safe, when delivering critical diagnosis information, a change in therapy or prescribing intensive treatment. If this is not an option, a video consultation should be considered, and the patient should be encouraged to have a support person with them to assist (Cancer Australia 2020a).

Principle 7: Research and clinical trials

Research and clinical trials play an important role in establishing the efficacy and safety of diagnostic, prognostic and therapeutic interventions, as well as establishing the role of psychological, supportive care and palliative care interventions (Sjoquist & Zalcberg 2013).

Clinical trials are the foundation for improved cancer outcomes, allowing new treatments to be tested and offering patients access to potentially more effective therapies than otherwise available to them.

Clinical trials are available for multiple types of cancer and may be a valuable option for people with rare, difficult-to-treat conditions for which there may be limited evidence about how the condition is best treated or managed (Australian Clinical Trials 2015).

Treating specialists and multidisciplinary teams should be aware of or search for clinical trials that may be suitable for their patients. Specialists should be willing to refer appropriate patients to other treating centres to participate in research or clinical trials at any stage of the care pathway and be willing to discuss the pros and cons of participating in such trials. Any member of the multidisciplinary team can encourage cross-referral between clinical trials centres. Possible ineligibility to participate in a clinical trial should be discussed with the patient. Acknowledge disappointment and offer support in this instance.

Health services should strive to implement policies and procedures that facilitate equitable access to clinical trials for all patients, including culturally diverse patients, regional patients and those from Aboriginal or Torres Strait Islander communities.

The use of telehealth technology, such as the Australasian Tele-trial Model, hopes to improve access to trials for patients being treated in rural and regional areas (COSA 2016).

Australian Cancer Trials is a national clinical trials database. It provides information on the latest clinical trials in cancer care, including trials that are recruiting new participants. Search for a trial <www.australiancancertrials.gov.au> via its website.

Education and training

Research and clinical trials provide an opportunity to educate health professionals who are in training. Cancer centres may be affiliated with teaching hospitals, universities or research groups to promote higher education or to develop the academic workforce, leading to more sustainable practice. Specialists should be encouraged to take up and retain active membership to professional societies and organisations that can assist with professional development opportunities.

Summary – optimal timeframes

Evidence-based guidelines, where they exist, should inform timeframes. Treatment teams need to recognise that shorter timeframes for appropriate consultations and treatment often promote a better experience for patients. Three steps in the pathway specify timeframes for care (Figure 3). They are designed to help patients understand the timeframes in which they can expect to be assessed and treated, and to help health services plan care delivery in accordance with expert-informed time parameters to meet the expectation of patients. These timeframes are based on expert advice from the Breast Cancer Working Group, recognising that they may not always be possible.

Figure 3: Timeframes for care

Step in pathway	Care point	Timeframe
Presentation, initial investigations and referral	Signs and symptoms	A patient with signs and symptoms that may suggest breast cancer should be seen by a GP within 2 weeks
	Initial investigations initiated by GP	Optimally, tests should be done within 2 weeks
	Referral to specialist	A positive result on any component of the triple test warrants specialist surgical referral. Ideally the surgeon should see the patient with proven or suspected cancer within 2 weeks of diagnosis. If necessary, prior discussion should facilitate referral
Diagnosis, staging and treatment planning	Diagnosis and staging	Diagnostic investigations should be completed within 2 weeks of the initial specialist consultation
	Multidisciplinary team meeting and treatment planning	Ideally, the multidisciplinary team should discuss all newly diagnosed patients with breast cancer prior to surgery or neoadjuvant chemotherapy Referral to a breast cancer nurse within 7 days of definitive diagnosis
Treatment	Surgery	Surgery should occur ideally within 5 weeks of the decision to treat (for invasive breast cancer)
	Chemotherapy and Systemic therapy	Neoadjuvant chemotherapy should begin within 4 weeks of the decision to treat Adjuvant chemotherapy should begin within 6 weeks of surgery Adjuvant chemotherapy for triple-negative breast and HER2-positive breast cancer should begin within 4 weeks of surgery Endocrine therapy should begin as soon as appropriate after completing chemotherapy, radiation therapy and/or surgery (and in some cases will be started in the neoadjuvant setting)
	Radiation therapy	For patients who don't have adjuvant chemotherapy, radiation therapy should begin within 8 weeks of surgery For patients who have adjuvant chemotherapy, radiation therapy should begin 3–4 weeks after chemotherapy

Optimal care pathway

Seven steps of the optimal care pathway

Step 1: Prevention and early detection

Step 2: Presentation, initial investigations and referral of patients with suspected breast cancer

Step 3: Diagnosis, staging and treatment planning

Step 4: Treatment

Step 5: Care after initial treatment and recovery

Step 6: Managing recurrent, residual or metastatic disease

Step 7: End-of-life care

Breast cancer is the most common cancer in Australian women, accounting for more than 29 per cent of newly diagnosed cancers. It is second only to lung cancer as the most common cause of death from cancer (AIHW 2019).

Breast cancer in men accounts for less than 1 per cent of all breast cancers, with 90 per cent of men diagnosed with breast cancer after the age of 50 (Cancer Australia 2016). The recommendations in this document apply to all patients unless otherwise specified.

Early breast cancer may or may not have spread to lymph nodes in the armpit. Advanced breast cancer comprises both locally advanced breast and metastatic breast cancer (Cardoso et al. 2018). Locally advanced breast cancer is breast cancer with extensive axillary nodal involvement and that may have spread to areas near the breast, such as the chest wall.

Step 1: Prevention and early detection

This step outlines recommendations for the prevention and early detection of breast cancer.

Evidence shows that not smoking, avoiding or limiting alcohol intake, eating a healthy diet, maintaining a healthy body weight, being physically active, being sun smart and avoiding exposure to oncoviruses or carcinogens may help reduce most cancer risk (Cancer Council Australia 2018).

1.1 Risk factors for female breast cancer

These are the *convincing* risk factors for developing breast cancer (Cancer Australia 2018) (those highlighted in **bold** are modifiable):

- age
- gender (being female)
- significant family history of breast cancer and/or other cancers
- pathogenic variants in cancer predisposition genes including BRCA1, BRCA2, CDH1, PALB2, PTEN, NF1, STK11, TP53, ATM and CHEK2
- DCIS (ductal carcinoma in situ)
- LCIS (lobular carcinoma in situ) also referred to as non-invasive lobular neoplasia
- atypical epithelial proliferative lesions (atypical ductal hyperplasia and atypical lobular hyperplasia)
- previous breast cancer
- high mammographic breast density (must be adjusted for age and body mass index)
- early menarche

- not bearing children
- never having breastfed
- late age at first birth
- late menopause
- maternal exposure to diethylstilboestrol (DES) in utero
- **use of combined hormone replacement therapy, particularly for extended periods over many years**
- **not engaging in adequate physically active**
- **overweight and obesity (only for postmenopausal women)**
- **weight gain (postmenopausal)**
- **alcohol consumption**
- **exposure of the breast to ionising radiation.**

For more information, visit the Cancer Australia breast cancer risk factor website <<https://breastcancerriskfactors.gov.au/>>.

1.2 Prevention

Recommendations that may assist in preventing breast cancer include:

- maintaining a healthy weight
- avoiding or limiting alcohol intake to no more than 10 standard drinks a week and no more than four standard drinks on any one day
- getting 30 minutes or more of moderate-intensity (puffing) exercise most days (150–300 minutes per week)
- avoiding or limiting hormone replacement therapy use
- additional prevention strategies in people with increased risk (e.g. gene mutation carriers).

Additional prevention interventions are considered for women at increased risk, including those at moderately increased risk. For example, those at moderately increased risk (1.5–3 times the population risk) may be offered medication to reduce risk, and those at high risk (more than three times the population risk) may be offered medication or risk-reducing surgery.

1.3 Risk reduction

Everyone should be encouraged to reduce their modifiable risk factors (see section 1.1).

1.3.1 Risk-reducing medication for women at moderate or high risk

For women assessed as having an increased risk of breast cancer, antihormonal risk-reducing medication such as tamoxifen, raloxifene or an aromatase inhibitor is an option to lower the risk of developing breast cancer. Decisions about whether to use risk-reducing medication should be based on an accurate risk assessment and clear understanding of the absolute benefits and risks for each individual woman. The benefits and risks for an individual can be assessed by using iPrevent <<https://www.petermac.org/iprevent>>.

1.3.2 Risk-reducing surgery for women at high risk

Risk-reducing surgery such as prophylactic bilateral mastectomy may be considered by women at high risk of developing breast cancer (NCI 2015), including those with a mutation in a major breast cancer predisposition gene such as BRCA1 or BRCA2 (Cancer Council Australia 2015).

Bilateral risk-reducing mastectomy reduces the absolute risk of breast cancer by at least 90 per cent (NCI 2015). Even with total mastectomy, not all breast tissue can be removed. The remaining breast tissue may be at risk of becoming cancerous in the future (NCI 2013).

Knowledge of a woman's risk factors can be used to objectively assess her individual breast cancer risk using a validated tool such as iPrevent <<https://www.petermac.org/iprevent>>.

1.4 Risk assessment tools

By accurately assessing a woman's personal breast cancer risk level, health professionals can offer the most appropriate evidence-based prevention and early detection strategies. All women should therefore consider having their individual breast cancer risk assessed. This can be done by women themselves or in primary care. Cancer risk assessment should be repeated when major risk factors change (e.g. new family cancer history, breast biopsy showing atypical hyperplasia or LCIS).

There are a number of validated computerised breast cancer risk assessment tools that estimate a woman's breast cancer risk based on her individual risk factors:

- iPrevent <<https://www.petermac.org/iprevent>>
- IBIS tool <<https://ibis.ikonopedia.com>>
- CanRisk Web Tool <<https://canrisk.org/>>.

iPrevent is an Australian tool designed for self-administration by women and collaborative use with clinicians and is the only tool that links the risk assessment directly to the relevant risk management guidelines.

In Australia, absolute lifetime population risk of breast cancer is 12 per cent, but most women are below this risk. Cancer Australia defines levels of breast cancer risk as follows:

- average risk: < 1.5 × population risk
- moderate risk: 1.5–3 × population risk
- high risk: > 3 × population risk (Cancer Australia 2010).

People with or without a personal history of breast cancer at high risk due to their family cancer history should be referred to a familial cancer service for further risk assessment and for possible genetic testing (eviQ 2019a). Consider referring:

- untested adult blood relatives of a person with a known pathogenic variant (mutation) in a breast and/or ovarian cancer predisposition gene (e.g. BRCA1 or BRCA2, TP53, PTEN, STK11, PALB2, CDH1, NF1) or
- people with two first- or second-degree relatives diagnosed with breast or ovarian cancer plus one or more of the following on the same side of the family:
 - additional relative(s) with breast or ovarian cancer
 - breast cancer diagnosed under age 50 years
 - more than one primary breast cancer in the same woman
 - breast and ovarian cancer in the same woman
 - Jewish ancestry
 - breast cancer in a male
 - pancreatic cancer
 - high-grade (\geq Gleason 7) prostate cancer.

Additionally, people with breast cancer should be referred to a familial cancer service if they meet the following criteria:

- male breast cancer at any age
- breast cancer and Jewish ancestry
- two primary breast cancers in the same person, where the first occurred under age 60 years
- two or more different but associated cancers in the same person at any age (e.g. breast and ovarian cancer)
- breast cancer aged under 40 years or triple-negative breast cancer aged under 50 years
- lobular breast cancer and a family history of lobular breast or diffuse-type gastric cancer
- breast cancer aged under 50 years with limited family structure or knowledge (e.g. adopted)
- breast cancer and a personal or family history suggestive of:
 - Peutz-Jegher syndrome (oral pigmentation and/or gastrointestinal polyposis)
 - PTEN hamartoma syndrome (macrocephaly, specific mucocutaneous lesions, endometrial or thyroid cancer)
 - Li-Fraumeni syndrome (breast cancer < 50 years, adrenocorticocarcinoma, sarcoma, brain tumours).

Referral can also be considered if finding a relevant germline mutation would have high clinical utility (e.g. would alter treatment of the current cancer).

1.5 Early detection

1.5.1 Screening recommendations

Asymptomatic women

A significant proportion of breast cancers are diagnosed through mammographic screening in women who are asymptomatic. Assess a woman's individualised risk to see whether a personalised screening regimen may be appropriate.

Early detection through screening mammography has several benefits including improved mortality rates, increased treatment options and improved quality of life (Cancer Australia 2015a). For women with small tumours at diagnosis (< 10 mm), there is a more than 95 per cent five-year survival rate (Cancer Australia 2012).

BreastScreen Australia services operate within the framework of a comprehensive set of national accreditation standards that specify requirements for the safety and quality of diagnostic tests, timeliness of services and multidisciplinary care.

State, territory and federally funded two-yearly mammographic screening is offered to asymptomatic women from the age of 50 to 74 years through the BreastScreen Australia program (although available after 40 years of age upon request).

A doctor's referral is not required for screening through BreastScreen Australia, but general practitioners' encouragement is a key factor in women's participation in screening.

Not all breast cancers are detectable on screening mammograms, and new cancers may arise in the interval between mammograms. Women should be aware of the look and feel of their breasts and report concerns to their general practitioner.

Women invited to screening should be provided with information about the risk and benefits of mammographic screening.

There is a 42 per cent reduction in risk of dying from breast cancer in screened women (AIHW 2018b) and a significant reduction in treatment intensity for patients diagnosed within a screening program.

Screening can lead to anxiety, additional investigations for non-malignant processes, over-diagnosis and treatment of cancers that may never have needed treatment. Over-diagnosis could occur due to lesions that may not progress to invasive cancer during the woman's lifetime. Some lesions that need investigation based on their imaging features turn out not to be cancer. Providing women with information on risks and benefits can assist them to make informed decisions around screening participation (Cancer Australia 2014).

For more information, see Cancer Australia's position statement on over-diagnosis <<http://canceraustralia.gov.au/publications-and-resources/position-statements/overdiagnosis-mammographic-screening>>.

If a woman is reported as having high mammographic density please refer to the IBIS risk tool <<https://ibis.ikonopedia.com>>.

Symptomatic people

People who have symptoms or signs of breast cancer require prompt investigation of their symptoms, including diagnostic imaging. Screening mammography is not recommended for these people because it may lead to false reassurance and delayed diagnosis.

Step 2: Presentation, initial investigations and referral of patients with suspected breast cancer

This step outlines the process for the general practitioner to initiate the right investigations and refer to the appropriate specialist in a timely manner. The types of investigations the general practitioner undertakes will depend on many factors, including access to diagnostic tests, the availability of medical specialists and patient preferences.

At least one-third of breast cancers are found in apparently asymptomatic women through routine breast cancer screening, and participation in BreastScreen Australia should be encouraged for eligible women. The remaining women have symptomatic presentations.

2.1 Signs and symptoms

The following signs and symptoms should be investigated:

- a persistent new lump or lumpiness, especially involving only one breast
- a change in the size or shape of a breast
- a change to a nipple, such as crusting, ulceration, redness or inversion
- a nipple discharge that occurs without manual expression
- a change in the skin of a breast such as redness, thickening or dimpling
- axillary mass(es)
- an unusual breast pain that does not go away (Cancer Australia 2020b; Walker et al 2014).

People with symptoms as described above should not attend BreastScreen because they will require diagnostic imaging either publicly or privately.

2.1.1 Timeframe for general practitioner consultation

A patient with signs and symptoms that may suggest breast cancer should be seen by a general practitioner **within two weeks**.

2.2 Assessments by the general practitioner for patients with suspected breast cancer

The types of investigation undertaken by a general practitioner depend on many factors including access to diagnostic tests and medical specialists and the patient's preferences. General practitioners should refer all patients with a suspicious sign or symptom to a breast assessment clinic.

General practitioner examinations and investigations should include a triple test of three diagnostic components:

- medical history and clinical breast examination
- imaging – mammography and/or ultrasound

- non-excision biopsy – preferably core biopsy (Cancer Australia 2017a; Farshid et al. 2019). Pathologists should expedite such testing as part of routine clinical care. Funding through the Medicare Benefits Schedule is accessible for receptor profile evaluation of screen-detected cancers, including immunohistochemistry for ER, PR and HER2 and, when necessary, in situ hybridisation to assess HER2 gene amplification. Fine-needle aspiration biopsy does not permit distinction between invasive cancer and in situ malignancy. Evaluation of grade and subtype are not reliable, and cytology is inappropriate for assessing a cancer’s receptor profile (ER, PR, HER2), critical for optimal treatment planning, including suitability of neoadjuvant therapy. Fine-needle aspiration cytology may be considered if the clinical and imaging features suggest a benign process, particularly a cystic lesion. If cytology results are non-diagnostic, atypical, suspicious or malignant, core biopsy is needed.

Based on the best available evidence, the triple test provides the most effective means of excluding breast cancer in patients with breast symptoms. A positive result on any component of the triple test warrants referral for specialist surgical assessment and/or further investigation, irrespective of any other normal test results. This implies that not all three components of the triple test need to be performed to reach the conclusion that appropriate referral is needed. The triple test is positive if any component is indeterminate, suspicious or malignant (Cancer Australia 2017a).

For screen-detected lesions, a 2020 review by Cancer Australia established that core biopsy (including vacuum-assisted core biopsy) is the procedure of choice for assessing most screen-detected breast abnormalities (Cancer Australia 2020c). Fine-needle aspiration in the screening setting is appropriate for simple cysts, some complex cystic lesions, axillary lymph nodes and rare situations where a core biopsy is hazardous or technically difficult.

BreastScreen Australia services take responsibility for screening and investigation of screen-detected lesions, including needle biopsies. After multidisciplinary assessment and review of results, recommendations are made for the next steps in management. The woman and her general practitioner are advised of these recommendations in writing. Surgery and ongoing care are typically not part of the BreastScreen program and must be coordinated by the general practitioner through appropriate surgical referral.

To enable timely treatment planning, including consideration of neoadjuvant therapies, it is preferable that the histologic findings, including the receptor profile results, be available in time for the patient’s first consultation with the treating surgeon. Information could be provided to patients to enable them to make an informed decision on neoadjuvant therapy. See Breast Cancer Trials ‘Neoadjuvant patient decision aid’ brochure <<https://www.breastcancertrials.org.au/file/44/neoadjuvant-patient-decision-aid>>.

2.2.1 Timeframe for completing investigations for patients with suspected breast cancer

Optimally, tests should be done **within two weeks**.

2.3 Initial referral

Any patient with symptoms suspicious of breast cancer can be referred for specialist assessment as first line. If the diagnosis of breast malignancy is confirmed or the results are inconsistent or indeterminate, referral to a BreastSurgANZ member breast surgeon is warranted. See BreastSurgANZ 'Find a surgeon' <<https://www.breastsurganz.org/find-a-surgeon>> for a directory.

Patients should be enabled to make informed decisions about their choice of specialist and health service. General practitioners should make referrals in consultation with the patient after considering the clinical care needed, cost implications (see referral options and informed financial consent on page 9), waiting periods, location and facilities, including discussing the patient's preference for health care through the public or the private system.

Referral for suspected or diagnosed breast cancer should include the following essential information to accurately triage and categorise the level of clinical urgency:

- important psychosocial history and relevant medical history
- family history, current symptoms, medications and allergies
- results of current clinical investigations (imaging and pathology reports with ER, PR and HER2 receptor profile)
- results of all prior relevant investigations
- notification if an interpreter service is required.

Many services will reject incomplete referrals, so it is important that referrals comply with all relevant health service criteria.

If access is via online referral, a lack of a hard copy should not delay referral.

The specialist should provide timely communication to the general practitioner about the consultation and should notify the general practitioner if the patient does not attend appointments.

Aboriginal and Torres Strait Islander patients will need a culturally appropriate referral. To view the optimal care pathway for Aboriginal and Torres Strait Islander people and the corresponding quick reference guide, visit the Cancer Australia website <<https://www.canceraustralia.gov.au/affected-cancer/atsi/resources-health>>. Download the consumer resources – *Checking for cancer* and *Cancer* from the Cancer Australia website <<https://www.canceraustralia.gov.au/affected-cancer/atsi/resources-people>>.

2.3.1 Timeframe for referring to a specialist

A positive result on any component of the triple test warrants specialist surgical referral. Ideally, the surgeon should see the patient with proven or suspected cancer **within two weeks** of diagnosis. If necessary, prior discussion should facilitate referral.

2.4 Support and communication

2.4.1 Supportive care

The patient's general practitioner should consider an individualised supportive care assessment where appropriate to identify the needs of an individual, their carer and family. Refer to appropriate support services as required. See validated screening tools mentioned in Principle 4 'Supportive care'.

A number of specific needs may arise for patients at this time:

- assistance for dealing with the emotional distress and/or anger of dealing with a potential cancer diagnosis, anxiety/depression, interpersonal problems and adjustment difficulties
- access to expert health professionals with specific knowledge about the psychosocial needs of breast cancer patients
- encouragement and support to increase levels of exercise (Cormie et al. 2018; Hayes et al. 2019).

For more information refer to the National Institute for Health and Care Excellence 2015 guidelines, *Suspected cancer: recognition and referral* <www.nice.org.uk/guidance/ng12/chapter/Recommendations-on-patient-support-safety-netting-and-the-diagnostic-process>.

For additional information on supportive care and needs that may arise for different population groups, see Appendices A, B and C.

2.4.2 Communication with patients, carers and families

The general practitioner is responsible for:

- providing patients with information that clearly describes to whom they are being referred, the reason for referral and the expected timeframes for appointments
- outlining their potential role and that of the primary care team throughout treatment and follow-up care (Cancer Australia 2020d)
- considering referral to a breast care nurse such as a McGrath breast care nurse <www.mcgrathfoundation.com.au/get-support/find-a-nurse/> or a nurse in a local breast cancer centre
- considering referral to Breast Cancer Network Australia's 'My Journey online tool' <<https://www.bcna.org.au/understanding-breast-cancer/resources/my-journey-online-tool/>> and local community-based support such as peer support
- requesting that patients notify them if the specialist has not been in contact within the expected timeframe
- considering referral options for patients living rurally or remotely
- supporting the patient while waiting for the specialist appointment (Cancer Council nurses are available to act as a point of information and reassurance during the anxious period of awaiting further diagnostic information; patients can contact 13 11 20 nationally to speak to a cancer nurse).

More information

Refer to Principle 6 'Communication' for communication skills training programs and resources.

Step 3: Diagnosis, staging and treatment planning

Step 3 outlines the process for confirming the diagnosis and stage of cancer and for planning subsequent treatment. The guiding principle is that interaction between appropriate multidisciplinary team members should determine the treatment plan.

3.1 Specialist investigations (diagnostic work-up for people with breast cancer)

The treatment team, after taking a medical history and making a medical examination of the patient, should undertake the following investigations under the guidance of a specialist:

- appropriate breast imaging tests including bilateral mammography and ultrasound (if conventional imaging is insufficient to help guide treatment, consider MRI)
- ultrasound of the axilla (including fine-needle aspiration of nodes if the axillary ultrasound is abnormal)
- breast core biopsy, if not already undertaken (which allows determination of breast cancer receptor profiles [ER, PR, HER2]).

Patients should be assessed for the possibility of a breast cancer predisposition gene and considered for genetic counselling/testing if appropriate. For more information refer to eviQ's *Referral guidelines for breast cancer risk assessment and consideration of genetic testing* <<https://www.eviq.org.au/cancer-genetics/referral-guidelines/1620-referral-guidelines-for-breast-cancer-risk-as>>.

3.1.1 Timeframe for completing investigations

Diagnostic investigations should be completed **within two weeks** of the initial specialist consultation.

3.1.2 Germline genetic testing (family risk)

People with breast cancer should be referred for genetic work-up early in their treatment journey if they fulfil germline testing criteria using CanRisk or the Manchester score, or have a triple-negative breast cancer under 50 years of age. Other factors pertaining to genetic work-up include a personal or family history suggestive of:

- Peutz-Jegher syndrome (oral pigmentation and/or gastrointestinal polyposis)
- PTEN hamartoma syndrome (macrocephaly, specific mucocutaneous lesions, endometrial or thyroid cancer)
- Li-Fraumeni syndrome (breast cancer < 50 years, adrenocorticocarcinoma, sarcoma, brain tumours).

Family history-based testing threshold can be assessed using the Manchester score APP.

In some cases certain pathological subtypes of cancer or tumour tests (immunohistochemistry or tumour genetic tests) may suggest an underlying inherited cancer predisposition, especially triple-negative breast cancers.

Genetic testing is sometimes able to identify the cause of cancer in a family and may be used to guide treatment for the affected people.

A familial cancer service assessment can determine if genetic testing is appropriate. Genetic testing is likely to be offered when there is at least a 10 per cent chance of finding a causative 'gene error' (pathogenic gene variant; previously called a mutation). Usually testing begins with a variant search in a person who has had cancer (a diagnostic genetic test). If a pathogenic gene variant is identified, variant-specific testing is available to relatives to see if they have or have not inherited the familial gene variant (predictive genetic testing).

Medicare funds some genetic tests via a Medicare Benefits Schedule item number. Depending on the personal and family history, the relevant state health system may fund public sector genetic testing.

Pre-test counselling and informed consent is required before any genetic testing. In some states the treating team can offer 'mainstream' diagnostic genetic testing, after which referral is made to a familial cancer service if a pathogenic gene variant is identified. The familial cancer service can provide risk management advice, facilitate family risk notification and arrange predictive genetic testing for the family.

Visit the Centre for Genetics Education website <www.genetics.edu.au/individuals-and-families/cancer-in-the-family> for basic information about cancer in a family.

For detailed information and referral guidelines for breast cancer risk assessment and consideration of genetic testing, read eviQ's *Referral guidelines for breast cancer risk assessment and consideration of genetic testing* <<https://www.eviq.org.au/cancer-genetics/adult/referral-guidelines/1620-referral-guidelines-for-breast-cancer-risk-as>>.

3.2 Staging investigations for distant disease

Routine staging with, for example, computed tomography (CT) and bone scan are not recommended for most patients with early breast cancer. For a patient presenting with de novo metastatic disease, see step 6.

Staging is appropriate for patients with confirmed locally advanced or nodal disease and for any patient with clinical symptoms or clinical suspicion of metastatic disease. PET scan may be the most appropriate modality.

More information

Visit the Cancer Institute New South Wales website for information about understanding the stages of cancer <www.cancer.nsw.gov.au/understanding-cancer/stages-of-cancer>.

3.3 Performance status

Patient performance status is a central factor in cancer care and should be clearly documented in the patient's medical record.

Performance status should be measured and recorded using an established scale such as the Karnofsky scale or the Eastern Cooperative Oncology Group (ECOG) scale.

People over the age of 70 years should undergo some form of geriatric assessment (COSA 2013; palliAGED 2018). Screening tools can be used to identify those patients in need of a comprehensive geriatric assessment (Decoster et al. 2015). This assessment can be used to help determine life expectancy and treatment tolerance and guide appropriate referral for multidisciplinary intervention that may improve outcomes (Wildiers et al. 2014).

3.4 Treatment planning

3.4.1 Key considerations beyond treatment recommendations

A number of factors should be considered at this stage:

- the patient's overall condition, life expectancy, decision-making capacity and results from a geriatric assessment if appropriate in those over the age of 70 years
- patient preferences and aims of treatment
- psychosocial screening/evaluation and support
- discussing the multidisciplinary team approach to care with the patient
- ensuring a breast care nurse is part of the multidisciplinary team
- appropriate and timely referral to an MDM
- considering if an interpreter is required
- pregnancy and fertility options, contraception and prevention of chemotherapy-induced menopause
- financial and social aspects
- support with travel and accommodation
- teleconferencing or videoconferencing as required.

3.4.2 Timing for multidisciplinary team planning

Discussion at an MDM is a core component of quality care (ASCO & ESMO 2006). All patients with a new diagnosis of breast cancer should be referred to an MDM for discussion. Ideally, the multidisciplinary team should discuss all newly diagnosed patients with breast cancer prior to surgery or neoadjuvant chemotherapy. Results of all relevant tests and imaging should be available for the MDM. To assist with the burden of demand, sites may streamline and prioritise the MDM discussion using agreed protocols. Patients should be offered a referral to a breast cancer nurse **within seven days** of a definitive diagnosis.

Patients may be discussed at several time points during their diagnosis and treatment. This can ensure patients are identified who may benefit from neoadjuvant systemic therapy, where surgical decisions are complex and in planning of reconstructive surgery and sequencing of therapies, or for relevant clinical trials.

3.4.3 Responsibilities of the multidisciplinary team

The multidisciplinary team requires administrative support in developing the agenda for the meeting, for collating patient information and to ensure appropriate expertise around the table to create an effective treatment plan for the patient. The MDM has a chair and multiple lead clinicians. Each patient case will be presented by a lead clinician (usually someone who has seen the patient before the MDM). In public hospital settings, the registrar or clinical fellow may take this role. A member of the team records the outcomes of the discussion and treatment plan in the patient history and ensures these details are communicated to the patient's general practitioner.

When developing treatment recommendations for each patient, MDM participants ensure:

- the tumour has been adequately staged
- all appropriate treatment modalities are considered
- psychosocial and medical comorbidities that may influence treatment decisions are considered
- the patient's treatment preferences are known and considered
- clinical trial eligibility, availability and participation are considered
- relevant optimal care pathway timeframes are considered.

The team should consider the patient's values, beliefs and cultural needs as appropriate to ensure the treatment plan is in line with these. There may be early consideration of post-treatment pathways at this point – for example, shared follow-up care.

MDMs should aim to develop and agree by consensus an individualised treatment plan for each patient discussed. At times when there is a divergence of opinion about a patient's management or equivalent options, these differing opinions should be discussed with the patient to enable them to make an informed decision. Patients should be given time to discuss treatment options with others before making this decision.

MDM recommendations should be communicated in a timely manner to the patient and referring doctor/general practitioner with formal documentation. Further details regarding MDM requirements can be found via the *Victorian cancer multidisciplinary team meeting quality framework* <<https://www2.health.vic.gov.au/about/health-strategies/cancer-care/cancer-services-framework/multidisciplinary-care>>.

3.4.4 Members of the multidisciplinary team for breast cancer

The multidisciplinary team should be composed of the core disciplines that are integral to providing good care. Team membership should reflect both clinical and supportive care aspects of care. Pathology and radiology expertise are essential.

See Appendix E for a list of team members who may be included in the multidisciplinary team for breast cancer.

Core members of the multidisciplinary team are expected to attend most MDMs either in person or remotely via virtual mechanisms. Additional expertise or specialist services may be required for some patients such as breast cancer patients during pregnancy. An Aboriginal and Torres Strait Islander cultural expert should be considered for all patients who identify as Aboriginal or Torres Strait Islander.

3.4.5 Responsibilities of individual team members

The general practitioner who made the referral is responsible for the patient until care is passed to another practitioner who is directly involved in planning the patient's care.

The general practitioner may play a number of roles in all stages of the cancer pathway including diagnosis, referral, treatment, shared follow-up care, post-treatment surveillance, coordination and continuity of care, as well as managing existing health issues and providing information and support to the patient, their family and carer.

A nominated contact person from the multidisciplinary team may be assigned responsibility for coordinating care in this phase. Care coordinators (usually a breast care nurse) are responsible for ensuring there is continuity throughout the care process and coordination of all necessary care for a particular phase (COSA 2015). The care coordinator may change over the course of the pathway.

The lead clinician is responsible for overseeing the activity of the team and for implementing treatment within the multidisciplinary setting.

3.5 Research and clinical trials

Patients should be encouraged to participate in research or clinical trials where available and appropriate.

For more information visit:

- Cancer Australia website <www.australiancancertrials.gov.au>
- Breast Cancer Trials website <<https://www.breastcancertrials.org.au/home>>.

3.6 Support and communication

3.6.1 Prehabilitation

Cancer prehabilitation uses a multidisciplinary approach combining exercise, nutrition and psychological strategies to prepare patients for the challenges of cancer treatment such as surgery, systemic therapy and radiation therapy. Team members may include anaesthetists, oncologists, surgeons, haematologists, clinical psychologists, exercise physiologists, physiotherapists and dietitians, among others.

Patient performance status is a central factor in cancer care and should be frequently assessed. All patients should be screened for malnutrition using a validated tool, such as the Malnutrition Screening Tool (MST). The lead clinician may refer obese or malnourished patients to a dietitian preoperatively or before other treatments begin.

Patients who currently smoke should be encouraged to stop smoking before receiving treatment. This should include an offer of referral to Quitline in addition to smoking cessation pharmacotherapy if clinically appropriate.

Evidence indicates that patients who respond well to prehabilitation may have fewer complications after treatment. For example, those who were exercising before diagnosis and patients who use prehabilitation before starting treatment may improve their physical or psychological outcomes, or both, and this helps patients to function at a higher level throughout their cancer treatment (Cormie et al. 2017; Silver 2015).

A key contact person, ideally a breast care nurse, should be agreed as soon as possible (within seven days is optimal) to support communication and coordination of patient-centred care. Consultations may be via telephone and/or videoconferencing, where appropriate (Cancer Australia 2020e).

For patients with breast cancer, the multidisciplinary team should consider these specific prehabilitation assessments and interventions for treatment-related complications or major side effects:

- conducting a physical and psychological assessment to establish a baseline function level
- identifying impairments and providing targeted interventions to improve the patient's function level (Silver & Baima 2013)
- reviewing the patient's medication to ensure optimisation and to improve adherence to medicine used for comorbid conditions. Some medications, such as anticoagulants, may need to be modified before surgery.

Following completion of primary cancer treatment, rehabilitation programs have considerable potential to enhance physical function.

See Breast Cancer Network Australia's 'Physical Preparation & Recovery After Breast Reconstruction' <<https://www.bcna.org.au/understanding-breast-cancer/treatment/breast-reconstruction/physical-preparation-recovery-after-breast-reconstruction/>>.

3.6.2 Fertility preservation and contraception

Cancer and cancer treatment may cause fertility problems. This will depend on the age of the patient, the type of cancer and the treatment received. Infertility can range from difficulty having a child to the inability to have a child. Infertility after treatment may be temporary, lasting months to years, or permanent (AYA Cancer Fertility Preservation Guidance Working Group 2014).

Patients need to be advised about and potentially referred for discussion about fertility preservation before starting treatment and need advice about contraception before, during and after treatment. Patients and their family should be aware of the ongoing costs involved in optimising fertility. Fertility management may apply in both men and women. Fertility preservation options are different for men and women and the need for ongoing contraception applies to both men and women.

The potential for impaired fertility should be discussed and reinforced at different time points as appropriate throughout the diagnosis, treatment, surveillance and survivorship phases of care. These ongoing discussions will enable the patient and, if applicable, the family to make informed decisions. All discussions should be documented in the patient's medical record.

More information

See the Cancer Council website <www.cancervic.org.au/living-with-cancer/common-side-effects/fertility/fertility-overview.html> for more information.

See Breast Cancer Network Australia's fertility video <<https://www.bcna.org.au/news/2019/12/fertility-resource/>> for more information.

3.6.3 Supportive care

See validated screening tools mentioned in Principle 4 'Supportive care'.

A number of specific challenges and needs may arise for patients at this time:

- assistance for dealing with psychological and emotional distress while adjusting to the diagnosis; treatment phobias; existential concerns; stress; difficulties making treatment decisions; anxiety or depression or both; psychosexual issues such as potential loss of fertility and premature menopause; history of sexual abuse; and interpersonal problems
- access to expert health professionals with specific knowledge about the psychosocial needs of breast cancer patients
- for some populations (culturally diverse backgrounds, Aboriginal people and lesbian, transgender and intersex communities) a breast cancer diagnosis comes with additional psychosocial complexities, and discrimination uncertainty may also make these groups less inclined to seek regular medical care – access to expert health professionals with specific knowledge about the psychosocial needs of these groups may be required
- preservation of ovarian function should be discussed before starting treatment – goserelin reduces the risk of chemotherapy-induced menopause and should particularly be discussed before chemotherapy for women with ER-negative breast cancer (for some women with ER-positive breast cancer it may also be appropriate to use goserelin before and during chemotherapy; see Breast Cancer Network Australia's *Fertility-related choices* booklet <https://www.bcna.org.au/media/7660/bcna_fertility-booklet-web_oct2019.pdf>)
- management of physical symptoms such as pain and fatigue (Australian Adult Cancer Pain Management Guideline Working Party 2019)
- upper limb and breast lymphoedema and cording following lymphadenectomy – this is a potential treatment side effect in people with breast cancer, which has a significant effect on survivor quality of life; referral (preferably preoperatively) to a health professional with accredited lymphoedema management qualifications, offering the full scope of complex lymphoedema therapy, should be encouraged
- limitations in upper limb movement and function, which may affect radiation therapy – referral to a physiotherapist may be required (prospective monitoring, particularly for high-risk patients is recommended)
- weight changes, which can be a significant issue for patients, and may require referral to a dietitian before, during and after treatment
- malnutrition or undernutrition, identified using a validated nutrition screening tool such as the MST (note that many patients with a high body mass index [obese patients] may also be malnourished [WHO 2018])
- support for families or carers who are distressed with the patient's cancer diagnosis
- support for families/relatives who may be distressed after learning of a genetically linked cancer diagnosis
- specific spiritual needs that may benefit from the involvement of pastoral/spiritual care
- financial and employment issues (such as loss of income and having to deal with travel and accommodation requirements for rural patients and caring arrangements for other family members).

Additionally, palliative care may be required at this stage.

For more information on supportive care and needs that may arise for different population groups, see Appendices A, B and C.

3.6.4 Communication with patients, carers and families

In discussion with the patient, the lead clinician should undertake the following:

- establish if the patient has a regular or preferred general practitioner and if the patient does not have one, then encourage them to find one
- provide written information appropriate to the health literacy of the patient about the diagnosis and treatment to the patient and carer and refer the patient to the *Guide to best cancer care* (consumer optimal care pathway) for breast cancer, as well as to relevant websites and support groups as appropriate
- refer the patient to Breast Cancer Network Australia's 'My Journey online tool' <<https://www.bcna.org.au/understanding-breast-cancer/resources/my-journey-online-tool/>>
- discuss the importance of relatives accessing predictive genetic testing when a pathogenic variant is identified in the patient
- provide a treatment care plan including contact details for the treating team and information on when to call the hospital
- discuss a timeframe for diagnosis and treatment with the patient and carer
- discuss the benefits of multidisciplinary care and gain the patient's consent before presenting their case at an MDM
- provide brief advice and refer to Quitline (13 7848) for behavioural intervention if the patient currently smokes (or has recently quit), and prescribe smoking cessation pharmacotherapy, if clinically appropriate
- recommend an 'integrated approach' throughout treatment regarding nutrition, exercise and minimal or no alcohol consumption among other considerations
- communicate the benefits of continued engagement with primary care during treatment for managing comorbid disease, health promotion, care coordination and holistic care
- where appropriate, review fertility needs with the patient and refer for specialist fertility management (including fertility preservation, contraception, management during pregnancy and of future pregnancies)
- be open to and encourage discussion about the diagnosis, prognosis (if the patient wishes to know) and survivorship and palliative care while clarifying the patient's preferences and needs, personal and cultural beliefs and expectations, and their ability to comprehend the communication
- encourage the patient to participate in advance care planning including considering appointing one or more substitute decision-makers and completing an advance care directive to clearly document their treatment preferences. Each state and territory has different terminology and legislation surrounding advance care directives and substitute decision-makers.

3.6.5 Communication with the general practitioner

Consider appointing one lead clinician at the time of initial diagnosis; however, all treating clinicians have these communication responsibilities:

- involving the general practitioner from the point of diagnosis
- ensuring regular and timely communication with the general practitioner about the diagnosis, treatment plan and recommendations from MDMs and inviting them to participate in MDMs (consider using virtual mechanisms)
- gathering information from the general practitioner including their perspective on the patient's psychosocial issues and comorbidities and locally available support services
- supporting the role of general practice both during and after treatment
- discussing shared or team care arrangements with general practitioners or regional cancer specialists, or both, together with the patient
- contributing to the development of a chronic disease and mental health care plan as required, particularly to access community supportive care service
- notifying the general practitioner if the patient does not attend appointments.

More information

Refer to Principle 6 'Communication' for communication skills training programs and resources.

Step 4: Treatment

Step 4 describes the optimal treatments for breast cancer, the training and experience required of the treating clinicians and the health service characteristics required for optimal cancer care.

All health services must have clinical governance systems that meet the following integral requirements:

- identifying safety and quality measures
- monitoring and reporting on performance and outcomes
- identifying areas for improvement in safety and quality (ACSQHC 2020).

Step 4 outlines the treatment options for breast cancer. For detailed clinical information on treatment options refer to this resource:

- Cancer Australia's *Guidance for the management of early breast cancer: recommendations and practice points* <<https://www.canceraustralia.gov.au/publications-and-resources/cancer-australia-publications/guidance-management-early-breast-cancer-recommendations-and-practice-points>>.

4.1 Treatment intent

The intent of treatment can be defined as one of the following:

- curative
- anti-cancer therapy to improve quality of life and/or longevity without expectation of cure
- symptom palliation.

The treatment intent should be established in a multidisciplinary setting, documented in the patient's medical record and conveyed to the patient and carer as appropriate.

The potential benefits need to be balanced against the morbidity and risks of treatment.

The appropriate clinician should discuss the advantages and disadvantages of each treatment and associated potential side effects with the patient and their carer or family before treatment consent is obtained and begins so the patient can make an informed decision. Supportive care services should also be considered during this decision-making process. Patients should be asked about their use of (current or intended) complementary/alternative therapies (see Appendix D).

Timeframes for starting treatment should be informed by evidence-based guidelines where they exist. The treatment team should recognise that shorter timeframes for appropriate consultations and treatment often promote a better experience for patients.

Initiate advance care planning discussions with patients before treatment begins (this could include appointing a substitute decision-maker and completing an advance care directive). Formally involving a palliative care team/service may benefit any patient, so it is important to know and respect each person's preference (AHMAC 2011).

4.2 Treatment options

The aim of treatment for breast cancer and the types of treatment recommended depend on the type, stage and location of the cancer and the patient's age, health and preferences.

4.2.1 Surgery

Early and locally advanced breast cancer is treated with curative intent.

Surgery for early breast cancer involves either breast-conserving surgery or mastectomy. Breast conserving surgery followed by radiation therapy is as effective as mastectomy for most patients with early breast cancer.

Patients with invasive breast cancer and a clinically and radiologically negative axilla should generally be offered sentinel node biopsy. Axillary treatment with surgery and/or radiation therapy should be considered for patients with nodal disease.

Oncoplastic breast surgery should be considered where appropriate to ensure the patient has the best possible outcome. Surgery may involve the breast surgeon and plastic surgeon working together because some reconstructions are very complex. It is important that patients are given enough time to consider their reconstructive options. This may require more than one appointment with the treating surgeon. It is the responsibility of the multidisciplinary team to ensure the patient is referred in a timely manner to allow for adequate planning of the surgery.

Breast reconstruction surgery

Mastectomy can be performed with or without immediate breast reconstruction. Patients should be fully informed of their options and offered the option of immediate or delayed reconstructive surgery if appropriate.

Timeframe for starting treatment

- Surgery should occur ideally **within five weeks** of the decision to treat (for invasive breast cancer).
- If being treated with neoadjuvant chemotherapy, surgery is deferred until **four to six weeks** after the completion of neoadjuvant chemotherapy, ensuring blood counts have recovered.

Training and experience required of the surgeon

- Breast surgeon (FRACS or equivalent, including membership of BreastSurgANZ) with adequate training and experience in breast cancer surgery and institutional agreed scope of practice within this area
- Plastic surgeon with an interest and expertise in breast reconstructive surgery and who contributes to the Australia Breast Device Registry

Documented evidence of the surgeon's training and experience, including their specific (sub-specialty) experience with breast cancer and procedures to be undertaken, should be available.

Health service characteristics

To provide safe and quality care for patients having surgery, health services should have access to:

- appropriate nursing and theatre resources to manage complex surgery
- a breast care nurse
- a multidisciplinary team
- critical care support
- 24-hour medical staff availability
- 24-hour operating room access and intensive care unit
- specialist pathology expertise
- diagnostic imaging
- in-house access to specialist radiology and nuclear medicine expertise.

4.2.2 Chemotherapy and other systemic therapy

If appropriate, goserelin for preventing chemo-induced menopause should begin at least one week prior to chemotherapy.

Neoadjuvant therapy, usually chemotherapy, may be appropriate for an increasing number of breast cancers, which may include tumours where the response to neoadjuvant chemotherapy may direct future therapy (e.g. triple-negative and HER2-positive cancers, locally advanced or inflammatory breast cancers as well as some larger operable breast cancers to down-stage tumours), either to make them operable or to allow breast-conserving therapy. The receptor profile of the breast cancer (ER, PR, HER2) assessed by pathologists on the core biopsy is essential in making decisions about the appropriateness and nature of neoadjuvant therapies.

For early breast cancers following surgery, a further discussion at the MDM will determine the appropriateness and type of systemic therapy. All patients with invasive cancer should be considered for systemic therapy.

Patients with LCIS and atypical hyperplasia should be considered for endocrine therapy (tamoxifen or anastrozole) to reduce future invasive breast cancer risk.

All patients with HER2-positive breast cancers (> 5 mm) should be considered for HER2-directed therapy. All patients with hormone receptor-positive breast cancer should be considered for antihormonal therapy. Endocrine therapy should be administered for five years and sometimes longer in higher risk cases.

A core biopsy is the recommended sample for evaluating receptor profile in breast cancer. The information about receptor profile should be made available to the treating teams including the pathologist evaluating the cancer resection specimen. This information helps to identify cases of discordance where further assessment is required and to reduce unnecessary repeat testing.

For patients who have not had a complete pathological response to neoadjuvant therapy, repeat assessment of receptor profile on the resected breast cancer tissue is required to plan ongoing treatment.

Adjuvant bisphosphonates improve survival and should be considered for selected patients being treated for breast cancer with curative intent.

Timeframes for starting treatment

- Neoadjuvant chemotherapy should begin **within four weeks** of the decision to treat with neoadjuvant chemotherapy.
- Adjuvant chemotherapy should begin **within six weeks** of surgery.
- Adjuvant chemotherapy for triple-negative breast and HER2-positive breast cancer should begin **within four weeks** of surgery.
- Endocrine therapy should **begin as soon as appropriate** after completing chemotherapy, radiation therapy and/or surgery (and in some cases will begin in the neoadjuvant setting).

Training and experience required of the appropriate specialists

Medical oncologists must have training and experience of this standard:

- Fellow of the Royal Australian College of Physicians or Medical Oncology Group of Australia (or equivalent)
- adequate training and experience that enables institutional credentialing and agreed scope of practice within this area (ACSQHC 2015).

Cancer (chemotherapy) nurses should have accredited training in these areas:

- anti-cancer treatment administration
- specialised nursing care for patients undergoing cancer treatments, including side effects and symptom management
- the handling and disposal of cytotoxic waste (ACSQHC 2020).

Systemic therapy should be prepared by a pharmacist whose background includes this experience:

- adequate training in systemic therapy medication, including dosing calculations according to protocols, formulations and/or preparation.

In a setting where no medical oncologist is locally available (e.g. regional or remote areas), some components of less complex therapies may be delivered by a general practitioner or nurse with training and experience that enables credentialing and agreed scope of practice within this area. This should be in accordance with a detailed treatment plan or agreed protocol, and with communication as agreed with the medical oncologist or as clinically required.

The training and experience of the appropriate specialist should be documented.

Health service characteristics

To provide safe and quality care for patients having systemic therapy, health services should have these features:

- a clearly defined path to emergency care and advice after hours
- access to diagnostic pathology including basic haematology and biochemistry, and imaging
- cytotoxic drugs prepared in a pharmacy with appropriate facilities
- occupational health and safety guidelines regarding handling of cytotoxic drugs, including preparation, waste procedures and spill kits (eviQ 2019b)
- guidelines and protocols to deliver treatment safely (including dealing with extravasation of drugs)
- coordination for combined therapy with radiation therapy, especially where facilities are not co-located
- appropriate molecular pathology access.

4.2.3 Radiation therapy

Radiation therapy is used to treat early, locally advanced, recurrent and metastatic breast cancer in conjunction with surgery and/or systemic treatments, depending on patient and disease factors.

In most cases, radiation therapy is recommended for patients with early breast cancer after breast-conserving surgery.

Hypofractionated radiation therapy (a three- to four-week course) should be considered for most patients with early breast cancer undergoing breast-conserving therapy.

Radiation therapy following mastectomy should be considered for selected patients.

Partial breast irradiation (including intraoperative radiation therapy or linac-based) can be considered for **selected** patients with early breast cancer.

Discussion at an MDM is essential.

Timeframe for starting treatment

- For patients who do not have adjuvant chemotherapy, radiation therapy should begin **within eight weeks** of surgery.
- For patients who have adjuvant chemotherapy, radiation therapy should begin **three to four weeks** after chemotherapy.

Training and experience required of the appropriate specialists

Radiation oncologist (FRANZCR or equivalent) with adequate training and experience that enables institutional credentialing and agreed scope of practice within this area.

The training and experience of the radiation oncologist should be documented.

Health service unit characteristics

To provide safe and quality care for patients having radiation therapy, health services should have these features:

- linear accelerator (LINAC) capable of image-guided radiation therapy (IGRT)
- dedicated CT planning
- access to MRI and PET imaging
- automatic record-verify of all radiation treatments delivered
- a treatment planning system
- trained medical physicists, radiation therapists and nurses with radiation therapy experience
- coordination for combined therapy with systemic therapy, especially where facilities are not co-located
- participation in Australian Clinical Dosimetry Service audits
- an incident management system linked with a quality management system.

4.3 Research and clinical trials

The team should support the patient to participate in research or clinical trials where available and appropriate. Many emerging treatments are only available on clinical trials that may require referral to certain trial centres.

For more information visit:

- Cancer Australia website <www.australiancancertrials.gov.au>
- Breast Cancer Trials website <www.breastcancertrials.org.au/home>.

4.4 Support and communication

4.4.1 Supportive care

See validated screening tools mentioned in Principle 4 'Supportive care'.

Assess the patient's response to all treatments using clinical outcome measures and patient-reported measures.

A number of specific challenges and needs may arise for patients at this time:

- assistance for dealing with emotional and psychological issues, including body image concerns, fatigue, quitting smoking, traumatic experiences, existential anxiety, treatment phobias, anxiety/depression, interpersonal problems and sexuality concerns
- access to expert health professionals with specific knowledge about the psychosocial needs of breast cancer patients
- potential isolation from normal support networks, particularly for rural patients who are staying away from home for treatment
- alteration of cognitive functioning in patients treated with chemotherapy and radiation therapy, which requires strategies such as maintaining written notes or a diary and repetition of information
- loss of fertility, sexual dysfunction or other symptoms associated with treatment or surgically or chemically induced menopause, which requires sensitive discussion and possible referral to a clinician skilled in this area
- general healthcare issues (e.g. smoking cessation and sleep disturbance), which can be referred to a general practitioner
- decline in mobility or functional status as a result of treatment
- management of physical symptoms such as pain, arthralgia and fatigue
- early management for acute pain postoperatively to avoid chronic pain
- side effects of chemotherapy such as neuropathy, cardiac dysfunction, nausea and vomiting; managing these side effects is important for improving quality of life
- managing complex medication regimens, multiple medications, assessment of side effects and assistance with difficulties swallowing medications – referral to a pharmacist may be required
- menopause symptoms, which may require referral to a menopause clinic
- upper limb problems following surgery including decreased range of movement, which may delay radiation therapy – referral to a physiotherapist may be required

- upper limb and breast lymphoedema following lymphadenectomy/radiation therapy – this is a potential treatment side effect in patients with breast cancer that has a significant effect on survivor quality of life; referral (preferably preoperatively) to a health professional with accredited lymphoedema management qualifications, offering the full scope of complex lymphoedema therapy, should be encouraged (prospective monitoring, particularly for high-risk patients is recommended)
- disfigurement and scarring from appearance-altering treatment (and possible need for a prosthetic), which may require referral to a specialist psychologist, psychiatrist or social worker
- weight changes – this may require referral to a dietitian before, during and after treatment
- bowel dysfunction, gastrointestinal or abdominal symptoms as a result of treatment, which may require support from a dietitian
- coping with hair loss and changes in physical appearance (refer to the Look Good, Feel Better program <<https://lgfb.org.au/>>; see ‘Resource list’ and/or consider scalp cooling)
- assistance with beginning or resuming regular exercise with referral to an exercise physiologist or physiotherapist (COSA 2018; Hayes et al. 2019).

Early involvement of general practitioners may lead to improved cancer survivorship care following acute treatment. General practitioners can address many supportive care needs through good communication and clear guidance from the specialist team (Emery 2014).

Patients, carers and families may have these additional issues and needs:

- financial issues related to loss of income (through reduced capacity to work or loss of work) and additional expenses as a result of illness or treatment
- advance care planning, which may involve appointing a substitute decision-maker and completing an advance care directive
- legal issues (completing a will, care of dependent children) or making an insurance, superannuation or social security claim on the basis of terminal illness or permanent disability.

Cancer Council’s 13 11 20 information and support line can assist with information and referral to local support services.

Breast Cancer Network Australia’s helpline (1800 500 258) and website <www.myjourney.org.au> can assist with information and support services.

For more information on supportive care and needs that may arise for different population groups, see Appendices A, B and C.

4.4.2 Rehabilitation

Rehabilitation may be required at any point of the care pathway. If it is required before treatment, it is referred to as prehabilitation (see section 3.6.1).

All members of the multidisciplinary team have an important role in promoting rehabilitation. Team members may include occupational therapists, speech pathologists, dietitians, social workers, psychologists, physiotherapists, exercise physiologists and rehabilitation specialists.

To maximise the safety and therapeutic effect of exercise for people with cancer, all team members should recommend that people with cancer work towards achieving, and then maintaining, recommended levels of exercise and physical activity as per relevant guidelines. Exercise should be prescribed and delivered under the direction of an accredited exercise physiologist or physiotherapist with experience in cancer care (Vardy et al. 2019). The focus of intervention from these health professionals is tailoring evidence-based exercise recommendations to the individual patient's needs and abilities, with a focus on the patient transitioning to ongoing self-managed exercise.

Other issues that may need to be dealt with include managing cancer-related fatigue, improving physical endurance, achieving independence in daily tasks, optimising nutritional intake, returning to work and ongoing adjustment to cancer and its sequels. Referrals to dietitians, psychosocial support, return-to-work programs and community support organisations can help in managing these issues.

4.4.3 Communication with patients, carers and families

The lead or nominated clinician should take responsibility for these important aspects of treatment:

- discussing treatment options with patients and carers, including the treatment intent and expected outcomes, and providing a written version of the plan and any referrals
- providing patients and carers with information about the possible side effects of treatment, managing symptoms between active treatments, how to access care, self-management strategies and emergency contacts
- encouraging patients to use question prompt lists and audio recordings, and to have a support person present to aid informed decision making
- offering advice to patients and carers on the benefits of and how to access support
- initiating a discussion about advance care planning and involving carers or family if the patient wishes.

4.4.4 Communication with the general practitioner

The general practitioner plays an important role in coordinating care for patients, including helping to manage side effects and other comorbidities, and offering support when patients have questions or worries. For most patients, simultaneous care provided by their general practitioner is very important.

The lead clinician, in discussion with the patient's general practitioner, should consider these points:

- the general practitioner's role in symptom management, supportive care and referral to local services
- using a chronic disease management plan and mental health care management plan
- how to ensure regular and timely two-way communication about:
 - the treatment plan, including intent and potential side effects
 - supportive and palliative care requirements
 - the patient's prognosis and their understanding of this
 - enrolment in research or clinical trials
 - changes in treatment or medications
 - the presence of an advance care directive or appointment of a substitute decision-maker
 - recommendations from the multidisciplinary team.

More information

Refer to Principle 6 'Communication' for communication skills training programs and resources.

Step 5: Care after initial treatment and recovery

The term ‘cancer survivor’ describes a person living with cancer, from the point of diagnosis until the end of life. Survivorship care in Australia has traditionally been provided to patients who have completed active treatment and are in the post-treatment phase. But there is now a shift to provide survivorship care and services from the point of diagnosis to improve cancer-related outcomes.

Cancer survivors may experience inferior quality of life and cancer-related symptoms for up to five years after their diagnosis (Jefford et al. 2017). Distress, fear of cancer recurrence, fatigue, obesity and sedentary lifestyle are common symptoms reported by cancer survivors (Vardy et al. 2019).

Due to an ageing population and improvements in treatments and supportive care, the number of people surviving cancer is increasing. International research shows there is an important need to focus on helping cancer survivors cope with life beyond their acute treatment. Cancer survivors often face issues that are different from those experienced during active treatment for cancer and may include a range of issues, as well as unmet needs that affect their quality of life (Lisy et al. 2019; Tan et al. 2019).

Physical, emotional and psychological issues include fear of cancer recurrence, cancer-related fatigue, pain, distress, anxiety, depression, cognitive changes and sleep issues (Lisy et al. 2019). Late effects may occur months or years later and depend on the type of cancer treatment. Survivors and their carers may experience impacted relationships and practical issues including difficulties with return to work or study and financial hardship. They may also experience changes to sex and intimacy. Fertility, contraception and pregnancy care after treatment may require specialist input.

The Institute of Medicine, in its report *From cancer patient to cancer survivor: Lost in transition*, describes the essential components of survivorship care listed in the paragraph above, including interventions and surveillance mechanisms to manage the issues a cancer survivor may face (Hewitt et al. 2006). Access to a range of health professions may be required including physiotherapy, occupational therapy, social work, dietetics, clinical psychology, fertility and palliative care. Coordinating care between all providers is essential to ensure the patient’s needs are met.

Cancer survivors are more likely than the general population to have and/or develop comorbidities (Vijayvergia & Denlinger 2015). Health professionals should support survivors to self-manage their own health needs and to make informed decisions about lifestyle behaviours that promote wellness and improve their quality of life (Australian Cancer Survivorship Centre 2016; Cancer Australia 2017b; NCSI 2015).

Breast Cancer Network Australia <www.myjourney.org.au> provides information and support designed specifically for the transition to life after treatment.

5.1 Transitioning from active treatment

The transition from active treatment to post-treatment care is critical to long-term health. In some cases, people will need ongoing, hospital-based care, and in other cases a shared follow-up care arrangement with their general practitioner may be appropriate. This will vary depending on the type and stage of cancer and needs to be planned.

Shared follow-up care involves the joint participation of specialists and general practitioners in the planned delivery of follow-up and survivorship care. A shared care plan is developed that outlines the responsibilities of members of the care team, the follow-up schedule, triggers for review, plans for rapid access into each setting and agreement regarding format, frequency and triggers for communication.

Shared follow-up care for early breast cancer is an innovative model of care that supports holistic follow-up and survivorship care following active treatment (Cancer Australia 2019c).

After completing initial treatment, a designated member of the multidisciplinary team (most commonly nursing or medical staff involved in the patient's care) should provide the patient with a needs assessment and treatment summary and develop a survivorship care plan in conjunction with the patient. This should include a comprehensive list of issues identified by all members of the multidisciplinary team involved in the patient's care and by the patient. These documents are key resources for the patient and their healthcare providers and can be used to improve communication and care coordination.

The **treatment summary** should cover, but is not limited to:

- the diagnostic tests performed and results
- diagnosis including stage, prognostic or severity score
- tumour characteristics
- treatment received (types and dates)
- current toxicities (severity, management and expected outcomes)
- interventions and treatment plans from other health providers
- potential long-term and late effects of treatment
- supportive care services provided
- follow-up schedule
- contact information for key healthcare providers.

5.2 Follow-up care and survivorship care plan

Responsibility for follow-up care should be agreed between the lead clinician, the general practitioner, relevant members of the multidisciplinary team and the patient. This is based on guideline recommendations for post-treatment care, as well as the patient's current and anticipated physical and emotional needs and preferences.

The options for follow-up should encompass the following:

- A follow-up schedule will be planned based on the patient's individual circumstances.
- Investigations should be determined on a case-by-case basis.
- Most follow-up will involve a history, including updating personal history and enquiry about persistent symptoms that might require investigation to exclude metastatic disease. Family cancer history should be updated.
- If the patient has previously had genetic testing that revealed an unclassified variant in a cancer predisposition gene, the clinician should liaise regularly with the relevant familial cancer service until the variant is classified as benign or pathogenic.
- In the case of a pathogenic variant, the clinician should prompt predictive testing in close blood relatives and recommend referral to a familial cancer service.
- Physical examination, and particularly breast examination and limb circumference measure, should be conducted. Annual mammography (unless the patient underwent a bilateral mastectomy) should be undertaken. In some cases it may be appropriate to also undertake breast ultrasound or MRI.
- Appropriate follow-up does not involve chest x-rays, bone scans, CT scans, positron emission tomography (PET) scans or blood tests unless the cancer has spread or there are symptoms suggesting metastases.
- Toxicity related to treatment should be monitored and managed, including bone health
- and cardiovascular health (Blaes & Konety 2020). There is a significant role for physiotherapy in preventing osteoporosis.
- Premenopausal women who develop amenorrhoea are at risk of rapid bone loss. There is evidence that oral bisphosphonates are effective in reducing bone loss.
- Continue to prompt general good health.

Adherence to ongoing recommended treatment such as endocrine therapy should be reviewed and side effects managed proactively to optimise adherence.

Evidence comparing shared follow-up care and hospital-based care indicates equivalence in outcomes including recurrence rate, cancer survival and quality of life (Cancer Research in Primary Care 2016).

Ongoing communication between healthcare providers involved in care and a clear understanding of roles and responsibilities is key to effective survivorship care.

In particular circumstances, other models of post-treatment care can be safely and effectively provided such as nurse-led models of care (Monterosso et al. 2019). Other models of post-treatment care can be provided in these locations or by these health professionals:

- in a shared care setting
- in a general practice setting
- by non-medical staff
- by allied health or nurses
- in a non-face-to-face setting (e.g. by telehealth).

A designated member of the team should document the agreed survivorship care plan. The survivorship care plan should support wellness and have a strong emphasis on healthy lifestyle changes such as a balanced diet, a non-sedentary lifestyle, weight management and a mix of aerobic and resistance exercise (COSA 2018; Hayes et al. 2019).

This survivorship care plan should also cover, but is not limited to:

- what medical follow-up is required (surveillance for recurrence or secondary and metachronous cancers, screening and assessment for medical and psychosocial effects)
- model of post-treatment care, the health professional providing care and where it will be delivered
- care plans from other health providers to manage the consequences of cancer and cancer treatment
- wellbeing, primary and secondary prevention health recommendations that align with chronic disease management principles
- rehabilitation recommendations
- available support services
- a process for rapid re-entry to specialist medical services for suspected recurrence.

Survivors generally need regular follow-up, often for five or more years after cancer treatment finishes. The survivorship care plan therefore may need to be updated to reflect changes in the patient's clinical and psychosocial status and needs.

Processes for rapid re-entry to hospital care should be documented and communicated to the patient and relevant stakeholders.

Care in the post-treatment phase is driven by predicted risks (e.g. the risk of recurrence, developing late effects of treatment and psychological issues) as well as individual clinical and supportive care needs. It is important that post-treatment care is based on evidence and is consistent with guidelines. Not all people will require ongoing tests or clinical review and may be discharged to general practice follow-up.

The lead clinician should discuss (and general practitioner reinforce) options for follow-up at the start and end of treatment. It is critical for optimal aftercare that the designated member of the treatment team educates the patient about the symptoms of recurrence.

General practitioners (including nurses) can:

- connect patients to local community services and programs
- manage long-term and late effects
- manage comorbidities
- provide wellbeing information and advice to promote self-management
- screen for cancer and non-cancerous conditions.

More information

Templates and other resources to help with developing treatment summaries and survivorship care plans are available from these organisations:

- Australian Cancer Survivorship Centre
- Cancer Australia – Principles of Cancer Survivorship
- Cancer Australia – Shared cancer follow-up and survivorship care: early breast cancer
- Cancer Council Australia and states and territories
- Clinical Oncology Society of Australia – Model of Survivorship Care
- eviQ – Cancer survivorship: introductory course
- MyCarePlan.org.au
- South Australian Cancer Service – Statewide Survivorship Framework resources
- American Society of Clinical Oncology – guidelines.

5.2.1 Preventing recurrence

Not smoking, eating a healthy diet, being sun smart, avoiding or limiting alcohol intake, being physically active and maintaining a healthy body weight may help reduce the risk of primary recurrence or a second primary cancer.

Encourage and support all cancer survivors to reduce modifiable risk factors for recurrence as well as other chronic diseases. Ongoing coordination of care between providers should also deal with any comorbidities, particularly ongoing complex and life-threatening comorbid conditions.

5.3 Research and clinical trials

Support cancer survivors to participate in research or clinical trials where they are available and appropriate. These might include studies to understand survivors' issues, to better manage treatment side effects, or to improve models of care and quality of life.

For more information visit:

- Cancer Australia website <www.australiancancertrials.gov.au>
- Breast Cancer Trials website <<https://www.breastcancertrials.org.au/home>>.

5.4 Support and communication

5.4.1 Supportive care

See validated screening tools mentioned in Principle 4 'Supportive care'. Additionally, the 'Cancer Survivors Unmet Needs (CaSun)' is another validated screening tool that may help health professionals to identify the unmet needs of patients during survivorship.

A number of specific challenges and needs may arise for cancer survivors, which may require support:

- access to expert health professionals with specific knowledge about the psychosocial needs of breast cancer patients
- family distress if familial cancer pathogenic variant is identified
- weight changes, which may be a significant issue for patients and may require referral to a dietitian
- menopause symptoms, which may require referral to a menopause clinic
- general healthcare issues (e.g. smoking cessation and sleep disturbance), which can be referred to a general practitioner
- management of physical symptoms such as pain, arthralgia and fatigue
- decline in mobility and/or functional status as a result of treatment, which may necessitate a referral to physiotherapy or occupational therapy
- upper limb and breast lymphoedema following lymphadenectomy/radiation therapy, which is a potential treatment side effect in patients with breast cancer that has a significant effect on survivor quality of life – referral to a health professional with accredited lymphoedema management qualifications, offering the full scope of complex lymphoedema therapy, may be needed
- bowel dysfunction, gastrointestinal or abdominal symptoms as a result of treatment, which may require support from a dietitian
- neuropathy, cardiac dysfunction, nausea and vomiting (managing these issues is important for improving quality of life)
- coping with hair loss (refer to the Look Good, Feel Better program <<https://lgfb.org.au/>>; see 'Resource list' and/or consider scalp cooling)
- managing complex medication regimens, multiple medications, assessment of side effects and assistance with difficulties swallowing medications, which may require referral to a pharmacist
- financial and employment issues (such as loss of income and assistance with returning to work, and the cost of treatment, travel and accommodation)
- appointing a substitute decision-maker and completing an advance care directive
- legal issues such as completing a will.

For more information on supportive care and needs that may arise for different population groups, see Appendices A, B and C.

5.4.2 Rehabilitation and recovery

Rehabilitation may be required at any point of the care pathway from the pre-treatment phase through to disease-free survival and palliative care (Cormie et al. 2017).

Issues that may need to be dealt with include managing cancer-related fatigue, coping with cognitive changes, improving physical endurance, achieving independence in daily tasks, returning to study or work and ongoing adjustment to cancer and its sequels.

Exercise is a safe and effective intervention that improves the physical and emotional health and wellbeing of cancer patients. Exercise should be embedded as part of standard practice in cancer care and be viewed as an adjunct therapy that helps counteract the adverse effects of cancer and its treatment.

Cancer survivors may find referral to specific cancer rehabilitation, optimisation programs or community-based rehabilitation appropriate and beneficial. Other options include referral to allied health supports through team care arrangements and mental health plans. Some community support organisations (cancer-related non-government, not-for-profit and charities) provide services to cancer survivors.

5.4.3 Communication with patients, carers and families

The lead clinician (themselves or by delegation) should take responsibility for these tasks:

- explaining the model of post-treatment care and the roles of health professionals involved in post-treatment care including the role of general practice
- explaining the treatment summary and follow-up care plan
- discussing the development of a shared follow-up and survivorship care plan where a model of shared follow-up care has been agreed
- discussing how to manage any of the physical, psychological or emotional issues identified
- providing information on the signs and symptoms of recurrent disease
- providing a survivorship care plan with information on secondary prevention and healthy living
- providing contact details of the care team involved
- providing clear information about the role and benefits of palliative care and advance care planning
- how to re-access specialist care if needed.

5.4.4 Communication with the general practitioner

The lead clinician should ensure regular, timely, two-way communication with the general practitioner about:

- the patient's progress
- the follow-up and survivorship care plan
- potential late effects
- supportive and palliative care requirements
- any shared care arrangements
- clarification of various roles in patient care
- a process for rapid re-entry to medical services for patients with suspected recurrence or if there are other concerns.

More information

Refer to Principle 6 'Communication' for communication skills training programs and resources.

Step 6: Managing recurrent, residual or metastatic disease

Patients who present with recurrent or metastatic disease should be managed by a multidisciplinary team and offered timely referral to appropriate physical, practical and emotional support.

Step 6 is concerned with managing recurrent or local residual and metastatic disease. The likelihood of recurrence depends on many factors usually related to the type of cancer, the stage of cancer at presentation and the effectiveness of treatment. Some cancers cannot be eradicated even with the best initial treatment. But controlling disease and disease-related symptoms is often possible, depending on the clinical situation.

For detailed information on treatment options for advanced breast cancer refer to the *5th ESO-ESMO International Consensus Guidelines for Advanced Breast Cancer (ABC 5)* <<https://www.esmo.org/guidelines/breast-cancer/consensus-recommendations-advanced-breast-cancer-abc-5>>.

6.1 Signs and symptoms of recurrent or metastatic disease

Consider the possibility of metastatic breast cancer if the patient has a symptom that persists over several weeks, tending to get worse rather than better and is otherwise unexplained.

Some cases of metastatic disease will be detected at the same time as presentation with the initial primary breast cancer ('de novo metastatic disease').

Signs and symptoms will depend on the type of cancer initially diagnosed and the location of metastatic disease. They may be discovered by the patient or by surveillance in the post-treatment period. Symptoms can often present as bone pain (most common), shortness of breath or cough, weight loss, abdominal symptoms or jaundice.

Other patients may present with symptoms of recurrent disease after a previous cancer diagnosis. Patients can present with symptoms of recurrent disease in the locoregional area, or at distant sites, or both. This may include a breast mass, skin nodules, enlarged lymph nodes or inflammatory cancer symptoms. Some local recurrence is detected at follow-up imaging only.

Some cases of recurrent disease will be detected by routine follow-up in a patient who is asymptomatic.

All cases should undergo investigation (staging scans) to establish the extent of disease and be rebiopsied if possible; biopsies should have receptor status re-evaluated.

Access to the best available therapies, including clinical trials, as well as treatment overseen by a multidisciplinary team, are crucial to achieving the best outcomes for anyone with metastatic or recurrent disease.

6.2 Managing recurrent or metastatic disease

Managing recurrent or metastatic disease is complex and should therefore involve all the appropriate specialties in a multidisciplinary team including palliative care where appropriate.

A rebiopsy of accessible sites and re-evaluation of breast cancer receptor profile should be undertaken. Non-bony sites are preferred because processing of bone specimens hinders evaluation of HER2 status.

A complete assessment of the sites of disease including CT of the abdomen and pelvis and of the chest plus bone scans, or PET-CT and blood tumour markers should also be undertaken. Brain CT or MRI may be required. Assessment of organ function and comorbidities are necessary.

From the time of diagnosis, the team should offer patients appropriate psychosocial care, supportive care, advance care planning and symptom-related interventions as part of their routine care. The approach should be personalised to meet the patient's individual needs, values and preferences. The full complement of supportive care measures as described throughout the optimal care pathway and in Appendices A, B and C should be offered to assist patients and their families and carers to cope. These measures should be updated as the patient's circumstances change.

Survivorship care should be considered and offered at an early stage. Many people live with advanced cancer for many months or years. As survival is improving in many patients, survivorship issues should be considered as part of routine care. Health professionals should therefore be ready to change and adapt treatment strategies according to disease status, prior treatment tolerance and toxicities and the patient's quality of life, in addition to the patient's priorities and life plans.

6.3 Multidisciplinary team

If there is an indication that a patient's cancer has returned, care should be provided under the guidance of a treating specialist. Each patient should be evaluated to determine if referral to the original multidisciplinary team is necessary. Often referral back to the original multidisciplinary team will not be necessary unless there are obvious aspects of care involving different therapeutic and supportive care disciplines not otherwise accessible. The multidisciplinary team may include new members such as palliative care specialists and metastatic breast cancer nurses. If a metastatic breast cancer nurse is not available, then a resident breast cancer nurse who cares for early and metastatic breast cancer patients may be included.

6.4 Treatment

Treatment will depend on the location, extent of recurrent disease, previous management and the patient's preferences and may include all modalities of therapies (surgery, radiation therapy and systemic therapy). Antiresorptive therapy may be warranted if bone metastases are present.

In most cases, a combination of anti-cancer and supportive therapies will provide the most effective overall management of recurrent disease.

Regular assessment of the patient's response to therapy should be undertaken and the therapy changed if disease progresses or as appropriate.

In patients with hormone receptor-positive breast cancer without rapidly progressing visceral disease, endocrine therapy combined with a CD4/6 inhibitor may be the most appropriate treatment initially with use of chemotherapy when endocrine responsiveness is lost.

Many endocrine therapies are effective in producing anti-tumour responses in metastatic breast cancer. These can often be used in sequence to gain successive responses to treatment. They include:

- ovarian ablation/suppression in premenopausal women
- selective oestrogen receptor modulators such as tamoxifen
- aromatase inhibitors, which block oestrogen production
- pure antioestrogen fulvestrant.

Treatment may focus on disease control or palliation based on the extent of disease, general health or the patient's preferences and values.

The potential goals of treatment should be discussed, respecting the patient's cultural values. Wherever possible, written information should be provided.

Encourage early referral to clinical trials or accepting an invitation to participate in research.

6.5 Advance care planning

Advance care planning is important for all patients with a cancer diagnosis but especially those with advanced disease. Patients should be encouraged to think and talk about their healthcare values and preferences with family or carers, appoint a substitute decision-maker and consider developing an advance care directive to convey their preferences for future health care in the event they become unable to communicate their wishes (AHMAC 2011).

More information

Refer to section 6.6 'More information' for links to resources.

Refer patients and carers to Advance Care Planning Australia <www.advancecareplanning.org.au> or to the Advance Care Planning National Phone Advisory Service on 1300 208 582.

6.6 Palliative care

Early referral to palliative care can improve the quality of life for people with cancer and in some cases may be associated with survival benefits (Haines 2011; Temel et al. 2010; Zimmermann et al. 2014). The treatment team should emphasise the value of palliative care in improving symptom management and quality of life to patients and their carers.

The lead clinician should ensure timely and appropriate referral to palliative care services. Referral to palliative care services should be based on the patient's need and potential for benefit, not prognosis.

Pain management intervention may be required. Palliative care services would preferably have access to interventional radiologists and pain services to assist with patients whose pain does not respond to conventional medications.

The 'Dying to Talk' resource may help health professionals when initiating discussions with patients about future care needs (see 'More information'). Ensure that carers and families receive information, support and guidance about their role in palliative care (Palliative Care Australia 2018).

The patient, with support from their family or carer and treating team, should be encouraged to consider appointing a substitute decision-maker and to complete an advance care directive.

More information

These online resources are useful:

- Advance Care Planning Australia <www.advancecareplanning.org.au>
- Care Search <www.caresearch.com.au/Caresearch/>
- Dying to Talk <www.dyingtotalk.org.au>
- the Palliative Care resource kit <www.health.gov.au/health-topics/palliative-care>
- Palliative Care Australia (for patients and carers) <www.palliativecare.org.au>.

6.7 Research and clinical trials

The treatment team should support the patient to participate in research and clinical trials where available and appropriate.

For patients with metastatic breast cancer, participation in clinical trials should be revisited by the multidisciplinary team due to alterations in the patient's disease such as resistance to current treatment or new trials available.

For more information visit the Cancer Australia website <www.australiancancertrials.gov.au>.

6.8 Support and communication

6.8.1 Supportive care

See validated screening tools mentioned in Principle 4 'Supportive care'.

A number of specific challenges and needs may arise at this time for patients:

- assistance for dealing with emotional and psychological distress resulting from fear of death or dying, existential concerns, anticipatory grief, communicating wishes to loved ones, interpersonal problems and sexuality concerns
- access to expert health professionals with specific knowledge about the psychosocial needs of breast cancer patients
- potential isolation from normal support networks, particularly for rural patients who are staying away from home for treatment
- cognitive changes as a result of treatment and disease progression such as altered memory, attention and concentration (a patient may appoint someone to make medical, financial and legal decisions on their behalf – a substitute decision-maker – before and in case they experience cognitive decline)
- decline in mobility or functional status as a result of recurrent disease and treatments (referral to physiotherapy or occupational therapy may be required)
- coping with hair loss and changes in physical appearance (refer to the Look Good, Feel Better program see 'Resource list')
- appointing a substitute decision-maker and completing an advance care directive
- financial issues as a result of disease recurrence such as gaining early access to superannuation and insurance
- legal issues (completing a will, care of dependent children) and making an insurance, superannuation or social security claim on the basis of terminal illness or permanent disability.

6.8.2 Rehabilitation

Rehabilitation may be required at any point of the metastatic care pathway, from preparing for treatment through to palliative care. Issues that may need to be dealt with include managing cancer-related fatigue, improving physical endurance, achieving independence in daily tasks, returning to work and ongoing adjustment to cancer and its sequels.

Exercise is a safe and effective intervention that improves the physical and emotional health and wellbeing of cancer patients. Exercise should be embedded as part of standard practice in cancer care and be viewed as an adjunct therapy that helps counteract the adverse effects of cancer and its treatment.

6.8.3 Communication with patients, carers and families

The lead clinician should ensure there is adequate discussion with patients and carers about the diagnosis and recommended treatment, including treatment intent and possible outcomes, likely adverse effects and the supportive care options available.

More information

Refer to Principle 6 'Communication' for communication skills training programs and resources.

Step 7: End-of-life care

Step 7 is concerned with maintaining the patient's quality of life and meeting their health and supportive care needs as they approach the end of life, as well as the needs of their family and carers.

Most patients with advanced cancer will reach a time when anti-cancer treatment is no longer appropriate. The team needs to share the principles of a palliative approach to care when making decisions with the patient and their family or carer. End-of-life care is appropriate when the patient's symptoms are increasing and functional status is declining.

Honest communication with patients is essential to ensure they have time to prepare and appropriate support is in place for their family and carers.

7.1 Multidisciplinary palliative care

If the treatment team does not include a palliative care member, the lead clinician should consider referring the patient to palliative care services, with the general practitioner's engagement. This may include inpatient palliative unit access (as required).

The multidisciplinary team may consider seeking additional expertise from these professionals:

- clinical psychologist
- clinical nurse specialist or practitioner
- social worker
- palliative medicine specialist
- pain specialist
- pastoral or spiritual carer
- bereavement counsellor
- music therapist
- art therapist
- cultural expert
- Canteen for children of parents with cancer <www.canteen.org.au/young-people/my-parent-has-cancer/>.

The team might also recommend that patients access these services:

- home and community-based care
- specialist community palliative care workers
- community nursing.

If the patient does not already have an advance care directive in place, a designated member of the treatment team should encourage them to develop one in collaboration with their family or carer (AHMAC 2011).

It is essential for the treatment team to consider the appropriate place of care, the patient's preferred place of death and the support needed for the patient, their family and carers.

The treatment team should also ensure that carers and families receive the information, support and guidance about their role according to their needs and wishes (Palliative Care Australia 2018).

More information

The treatment team can refer patients and carers to these resources:

- Palliative Care Australia <www.palliativecare.org.au>
- Advance Care Planning Australia <www.advancecareplanning.org.au> or to Advance Care Planning Australia's National Advisory Service on 1300 208 582.

7.2 Research and clinical trials

Clinical trials may help improve palliative care and in managing a patient's symptoms of advanced cancer (Cancer Council Victoria 2019). The treatment team should support the patient to participate in research and clinical trials where available and appropriate.

For more information visit the Cancer Australia website <www.australiancancertrials.gov.au>. See 'Resource list' for additional clinical trial databases.

7.3 Support and communication

7.3.1 Supportive care

See validated screening tools mentioned in Principle 4 'Supportive care'.

A number of specific challenges and needs may arise for patients at this time:

- assistance for dealing with emotional and psychological distress from anticipatory grief, fear of death or dying, anxiety/depression and interpersonal problems
- access to expert health professionals with specific knowledge about the psychosocial needs of patients
- management of physical symptoms including pain and fatigue
- decline in mobility or functional status, affecting the patient's discharge destination (a referral to physiotherapy, exercise physiology, occupational therapy or social work may be needed)
- appointing a substitute decision-maker and completing an advance care directive
- legal issues (completing a will, care of dependent children) and making an insurance, superannuation or social security claim on the basis of terminal illness or permanent disability
- specific support for families where a parent is dying and will leave behind bereaved children or adolescents, creating special family needs
- arranging a funeral.

These services and resources can help:

- referral to 13 11 20 for Cancer Council Australia's Pro Bono Program for free legal, financial, small business accounting and workplace assistance (subject to a means test)
- *Sad news sorry business* (Queensland Health 2015) for the specific needs of Aboriginal and Torres Strait Islander people.

For more information on supportive care and needs that may arise for different population groups, see Appendices A, B and C.

7.3.2 Communication with patients, carers and families

The lead clinician is responsible for:

- being open to and encouraging discussion with the patient about the expected disease course, considering the patient's personal and cultural beliefs and expectations
- discussing palliative care options, including inpatient and community-based services as well as dying at home and subsequent arrangements
- providing the patient and carer with the contact details of a palliative care service
- referring the patient to palliative care in the community according to the carer's wishes.

7.3.3 Communication with the general practitioner

The lead clinician should discuss end-of-life care planning to ensure the patient's needs and goals are met in the appropriate environment. The patient's general practitioner should be kept fully informed and involved in major developments in the patient's illness path.

More information

For support with communication skills and training programs, see these sources:

- *Sad news sorry business* <www.health.qld.gov.au/__data/assets/pdf_file/0023/151736/sorry_business.pdf>
- Principle 6 'Communication'.

Contributors and reviewers

Our thanks to the following health professionals, consumer representatives, stakeholders and organisations consulted in developing this optimal care pathway.

Expert working group (this edition)

Appendix A: Supportive care domains

Supportive care in cancer refers to the following five domains:

- the physical domain, which includes a wide range of physical symptoms that may be acute, relatively short lived or ongoing, requiring continuing interventions or rehabilitation
- the psychological domain, which includes a range of issues related to the patient’s mental health wellbeing and personal relationships
- the social domain, which includes a range of social and practical issues that will affect the patient, carer and family such as the need for emotional support, maintaining social networks and financial concerns
- the information domain, which includes access to information about cancer and its treatment, recovery and survivorship support services and the health system overall
- the spiritual domain, which focuses on the patient’s changing sense of self and challenges to their underlying beliefs and existential concerns (Palliative Care Victoria 2019).

Fitch’s (2000) model of supportive care recognises the variety and level of intervention required at each critical point as well as the need to be specific to the individual patient (Figure A1). The model targets the type and level of intervention required to meet patients’ supportive care needs.

Figure A1: Fitch’s tiered approach to supportive care

Appendix B: Psychological needs

Consider a referral to a psychologist, psychiatrist, pastoral/spiritual care practitioner, social worker, specialist nurse or a relevant community-based program if the patient has these issues:

- displaying emotional cues such as tearfulness, distress that requires specialist intervention, avoidance or withdrawal
- being preoccupied with or dwelling on thoughts about cancer and death
- displaying fears about the treatment process or the changed goals of their treatment
- displaying excessive fears about cancer progression or recurrence
- worrying about loss associated with their daily function, dependence on others and loss of dignity
- becoming isolated from family and friends and withdrawing from company and activities that they previously enjoyed
- feeling hopeless and helpless about the effect that cancer is having on their life and the disruption to their life plans
- struggling to communicate with family and loved ones about the implications of their cancer diagnosis and treatment
- experiencing changes in sexual intimacy, libido and function
- struggling with the diagnosis of metastatic or advanced disease
- having difficulties quitting smoking (refer to Quitline on 13 7848) or with other drug and alcohol use
- having difficulties transitioning to palliative care.

Additional considerations that may arise for the multidisciplinary team include:

- support for the carer – encourage referrals to psychosocial support from a social worker, psychologist or general practitioner
- referral to an exercise physiologist or physiotherapist as a therapeutic approach to prevent and manage psychological health
- referral to wellness-after-cancer programs to provide support, information and offer strategies.

Appendix C: Special population groups

The burden of cancer is not evenly spread across Australia. People experiencing socioeconomic disadvantage, Aboriginal and Torres Strait Islander communities, culturally diverse communities, people living with a disability, people with chronic mental health or psychiatric concerns and those who live in regional and rural areas of Australia have poorer cancer outcomes.

Aboriginal and Torres Strait Islander people

Cancer is the third leading cause of burden of disease for Aboriginal and Torres Strait Islander people. While Australia's cancer survival rates are among the best in the world, Aboriginal and Torres Strait Islander people continue to experience a different pattern of cancer incidence and significant disparities in cancer outcomes compared with non-Indigenous Australians.

For Aboriginal and Torres Strait Islander people, health and connection to land, culture, community and identity are intrinsically linked. Health encompasses a whole-of-life view and includes a cyclical concept of life–death–life.

The distinct epidemiology of cancer among Aboriginal and Torres Strait Islander people, and unique connection to culture, highlight the need for a specific optimal care pathway for Aboriginal and Torres Strait Islander people with cancer. Ensuring this pathway is culturally safe and supportive is vital to tackling the disparities for Aboriginal and Torres Strait Islander people.

Published in 2018, the *Optimal care pathway for Aboriginal and Torres Strait Islander people with cancer* provides guidance to health practitioners and service planners on optimal care for Aboriginal and Torres Strait Islander people with cancer across the cancer continuum.

In addition to the key principles underpinning cancer-specific pathways, these are the key concepts that are fundamental to Aboriginal and Torres Strait Islander health:

- providing a holistic approach to health and wellbeing
- providing a culturally appropriate and culturally safe service
- acknowledging the diversity of Aboriginal and Torres Strait Islander peoples
- understanding the social determinants and cultural determinants of health (Cancer Australia 2015).

To view the *Optimal care pathway for Aboriginal and Torres Strait Islander people with cancer*, visit the Cancer Australia website <<https://www.canceraustralia.gov.au/affected-cancer/atsi/resources-health>>. To view the consumer resources – *Checking for cancer* and *Cancer*, visit the Cancer Australia website <<https://www.canceraustralia.gov.au/affected-cancer/atsi/resources-people>>.

Culturally diverse communities

For people from culturally diverse backgrounds in Australia, a cancer diagnosis can come with additional complexities, particularly when English proficiency is poor. In many languages there is not a direct translation of the word 'cancer', which can make communicating vital information difficult. Perceptions of cancer and related issues can differ greatly in people from culturally diverse backgrounds and this can affect their understanding and decision making after a cancer diagnosis. In addition to different cultural beliefs, when English language is limited there is potential for miscommunication of important information and advice, which can lead to increased stress and anxiety for patients.

A professionally trained interpreter (not a family member or friend) should be made available when communicating with people with limited English proficiency. Navigation of the Australian healthcare system can pose problems for those with a non-Anglo culture, and members of the treatment teams should pay particular attention to supporting these patients.

The Australian Cancer Survivorship Centre has developed a glossary of more than 700 cancer terms in nine different languages. The multilingual glossary has been designed as a resource for professional translators, interpreters and bilingual health professionals working in the cancer field. The glossary is a unique tool that enables language professionals with access to accurate, consistent and culturally appropriate terminology.

Visit the Peter Mac website <www.petermac.org/multilingualglossary> to see the glossary.

People with disabilities

Disability, which can be physical, intellectual or psychological, may have existed before the cancer diagnosis or may be new in onset (occurring due to the cancer treatment or incidentally). Adjusting to life with a disability adds another challenge to cancer care and survivorship.

Several barriers prevent people with disabilities from accessing timely and effective health care (AIHW 2017):

- physical limitations
- competing health needs
- the trauma of undergoing invasive procedures
- potential barriers associated with obtaining informed consent
- failure to provide assistance with communication
- lack of information
- discriminatory attitudes among healthcare staff.

In caring for people with disabilities and a cancer diagnosis, the Australian Institute of Health and Welfare disability flag should be used at the point of admittance to correctly identify and meet the additional requirements of a person with disability. Facilities should actively consider access requirements, and health practitioners should make reasonable adjustments where required.

Patients aged between seven and 65 years who have a permanent or significant disability may be eligible for support or funding through the National Disability Insurance Scheme (National Disability Insurance Agency 2018). More information can be found on the NDIS website <www.ndis.gov.au>.

Patients aged 65 years or older (50 years or older for Aboriginal or Torres Strait Islander people) may be eligible for subsidised support and services through aged care services. An application to determine eligibility can be completed online over the phone. More information can be found at the My Aged Care website <www.myagedcare.gov.au>.

More information

'Talking End of Life' is a resource that shows how to teach people with intellectual disability about end of life. It is designed for disability support workers but is also helpful for others including families, health professionals and educators.

To view the resource, visit the Talking End of Life website <www.caresearch.com.au/tel/tabid/4881/Default.aspx>.

Older people with cancer

Planning and delivering appropriate cancer care for older people can present a number of challenges. This could also be true for frail people or those experiencing comorbidities. Effective communication between oncology and geriatrics departments will help facilitate best practice care, which takes into account physiological age, complex comorbidities, risk of adverse events and drug interactions, as well as the implications of cognitive impairment on suitability of treatment and consent (Steer et al. 2009).

At a national interdisciplinary workshop convened by the Clinical Oncology Society of Australia, it was recommended that people over the age of 70 undergo some form of geriatric assessment, in line with international guidelines (COSA 2013; palliAGED 2018). Screening tools can be used to identify those patients in need of a comprehensive geriatric assessment (Decoster et al. 2015). This assessment can be used to help determine life expectancy and treatment tolerance and guide appropriate referral for multidisciplinary intervention that may improve outcomes (Wildiers et al. 2014).

Frailty is not captured through traditional measures of performance status (e.g. ECOG) and includes assessment in the domains of:

- function
- comorbidity
- presence of geriatric syndromes
- nutrition
- polypharmacy
- cognition
- emotional status
- social supports.

Younger women

While there is no accepted definition of 'young' regarding breast cancer, younger women have been defined in previous guidelines as women aged 40 or younger at breast cancer diagnosis (Poggio et al. 2018). In 2020, it was estimated that 23 per cent of all new cancer cases diagnosed for Australian women aged 20–39 were for breast cancer (Cancer Australia 2020f). Younger women with breast cancer are likely to face different challenges including:

- early menopause
- fertility and sexuality issues
- role functions including partnering, caring for young children, education and carer issues
- self-image.

Compared with older women, these concerns may contribute to higher levels of psychological distress following diagnosis.

Pregnancy-associated breast cancer

Pregnancy-associated breast cancer, defined as breast cancer diagnosed during pregnancy or in the year after a pregnancy, accounts for 7 per cent of breast cancers in young women (Ives 2009), which is around 100 women annually in Australia. These women typically have a higher disease stage and more aggressive tumour features at diagnosis. However, when matched by age and disease stage with other breast cancer cases, there appears to be no survival difference, except in women diagnosed in the postpartum period, who have higher mortality and increased distant recurrence even after accounting for these factors.

There is an increased incidence of pre-term delivery for this group and management by a multidisciplinary team experienced in caring for these patients is recommended, with consideration given to the optimal time and type of delivery.

A multidisciplinary team approach is essential in managing this group. Initial investigation of any breast symptom in a pregnant or lactating woman should be the same as any other woman, to avoid diagnostic delays. The treating team should include health professionals involved in the treatment of breast cancer, the care of pregnancy and psychosocial support. The recommended obstetric and cancer management of a woman presenting with gestational breast cancer will depend on the fetal gestation and disease status at diagnosis.

Men with breast cancer

In 2020, the estimated number of men diagnosed with breast cancer in Australia is 167 (Cancer Australia 2019d). While breast cancer is uncommon in males, it is important for men who find changes in their breasts to see their doctor without delay. Given the low number of diagnoses and the identification of breast cancer in the general community as a 'female disease', many men who are diagnosed with breast cancer can feel isolated and unsupported. This has the potential to cause significant psychological distress and may lead to anxiety and depression. Those working in the area should be alert to the increased risk for psychological complications, the impact on body image and the potential for isolation. Peer support may be useful to normalise the feeling and side effects of treatment. All resources should be cognisant of not excluding men because this has the potential to further ostracise an already isolated group.

Breast Cancer Network Australia's 'My Journey online tool' <<https://www.bcna.org.au/understanding-breast-cancer/resources/my-journey-online-tool/>> has information specifically designed for men. Early referral for breast cancer will assist with some of the stigma associated with breast cancer in men and ensure men can connect with others after diagnosis.

People experiencing socioeconomic disadvantage

In general, people from lower socioeconomic groups are at greater risk of poor health, have higher rates of illness, disability and death, and live shorter lives than those from higher socioeconomic groups (AIHW 2016). People experiencing socioeconomic disadvantage are less likely to participate in screening programs, more likely to be obese, less likely to exercise and much more likely to smoke, which are all risk factors for cancer. In 2010–2014 age-standardised cancer incidence rates were higher in the lowest socioeconomic areas compared with the highest socioeconomic areas for all cancers combined (Cancer Australia 2019b).

Socioeconomic status and low health literacy are closely correlated. Therefore, effective communication with patients and carers is particularly important given the prevalence of low health literacy in Australia (estimated at 60 per cent of Australian adults) (ACSQHC 2014).

Consideration should be taken for cancer patients experiencing socioeconomic disadvantage to reduce their risk of being underserved for health care.

People with chronic mental health or psychiatric concerns

A diagnosis of cancer may present additional challenges to people who have pre-existing chronic mental health or psychiatric concerns, resulting in exacerbation of their mental health symptoms. This may include heightened anxiety, worsening depression or thoughts of self-harm.

As poor adjustment and coping can affect treatment decisions, people who are known to have a mental health diagnosis need psychosocial assessment in the oncology setting to formulate a plan for ongoing support throughout treatment.

Psychosocial support can assist with challenges in communicating with health professionals, enhance understanding of the treatment journey, ensure capacity for consent to treatment options and improve compliance with treatment requests. A referral for psychosocial support from a health professional to the psycho-oncology team can ensure these patients are provided with targeted interventions or referrals to community-based services that may mitigate problems associated with the impacts of social isolation that frequently accompany chronic mental ill-health.

Many patients with chronic mental health problems may be well known to external service providers. Psycho-oncology health professionals can form meaningful partnerships with existing service providers to optimise patient care throughout treatment and beyond.

Drug use disorders fall within the area of mental health conditions. People who are opiate dependent may have specific and individual requirements regarding pain management and their own preference for type of opiate prescribed or used.

Sexually and gender diverse groups

People who identify as sexually or gender diverse may have unique needs following a cancer diagnosis. Sexually or gender diverse identities include (but are not limited to) people who identify as lesbian, gay, bisexual or transgender, collectively 'LGBT'. There is no universally agreed upon initialism to describe this community, with other terms such as queer/questioning (Q), intersex (I), asexual (A) and pansexual (P) often included, as well as a plus symbol (+) indicating inclusivity of other identities not explicitly mentioned.

Sexual orientation and gender identity are relevant across the entire spectrum of cancer care, from prevention to survivorship and end-of-life care. LGBT people are less likely to participate in cancer screening, and some segments of the LGBT community exhibit elevated rates of specific cancer risk factors – for example, higher rates of smoking and alcohol use. Regarding treatment, there may be unique factors relevant to LGBT people that may affect decision making. Additionally, the LGBT population experiences higher rates of anxiety, depression and stressful life circumstances, and may be at risk of inferior psychosocial outcomes following a cancer diagnosis. LGBT people are also more likely to be estranged from their families of origin, and for older people, less likely to have adult children who may provide support and care.

Barriers to care for LGBT people include past negative interactions with healthcare systems, experiences or fear of discrimination and harassment in healthcare settings, assumptions of cisgender/heterosexual identity, lack of recognition or exclusion of same-sex partners from care, and a lack of relevant supportive care and information resources.

To provide safe and appropriate care for LGBT people with cancer, healthcare providers should:

- display environmental cues to show an inclusive and safe setting for LGBT patients
- avoid assumptions about the sexual orientation or gender identity of patients and their partners
- facilitate positive disclosure of sexual orientation or gender identity
- include same-sex/gender partners and families of choice in care
- be aware of relevant supportive care and information resources
- provide non-judgemental, patient-centred care.

Appendix D: Complementary therapies

Complementary therapies may be used together with conventional medical treatments to support and enhance quality of life and wellbeing. They do not aim to cure the patient's cancer. Instead, they are used to help control symptoms such as pain and fatigue (Cancer Council Australia 2019).

The lead clinician or health professional involved in the patient's care should discuss the patient's (or intended use) of complementary therapies not prescribed by the multidisciplinary team to assess safety and efficacy and to identify any potential toxicity or drug interactions.

The lead clinician should seek a comprehensive list of all complementary and alternative medicines being taken and explore the patient's reason for using these therapies and the evidence base. A transparent and honest discussion that is free from judgement should be encouraged.

While some complementary therapies are supported by strong evidence, others are not. For such therapies, the lead clinician should discuss their potential benefits and use them alongside conventional therapies (NHMRC 2014).

If the patient expresses an interest in using complementary therapies, the lead clinician should consider referring patients to health providers within the multidisciplinary team who have expertise in the field of complementary and alternative therapies (e.g. a clinical pharmacist, dietitian or psychologist) to assist them to reach an informed decision. Costs of such approaches should be part of the discussion with the patient and considered in the context of evidence of benefit.

The lead clinician should assure patients who use complementary therapies that they can still access a multidisciplinary team review and encourage full disclosure about therapies being used.

More information

- See Cancer Australia's position statement on complementary and alternative therapies <www.canceraustralia.gov.au/publications-and-resources/position-statements/complementary-and-alternative-therapies>.
- See the Clinical Oncological Society of Australia's position statement *Use of complementary and alternative medicine by cancer patients* <www.cosa.org.au/publications/position-statements.aspx>.

Appendix E: Members of the multidisciplinary team for breast cancer

The multidisciplinary team should include the following members:

- breast surgeon
- medical oncologist
- nurse(s) (with appropriate expertise such as a breast care nurse)
- pathologist
- radiation oncologist
- radiologist.

The multidisciplinary team may include the following members:

- Aboriginal health practitioner, Indigenous liaison officer or remote general practitioner
- care coordinator
- clinical trial nurse/coordinator
- dietitian
- exercise physiologist
- fertility specialist
- general practitioner
- geneticist and/or genetic counsellor
- lymphoedema physiotherapist/specialist
- occupational therapist
- pain specialist
- palliative care specialist
- pharmacist
- physiotherapist
- plastic surgeon
- psychologist
- psychiatrist
- reconstructive surgeon
- social worker
- spiritual/pastoral care.

Resource list

For patients, families and carers

Advance Care Planning Australia

Advance Care Planning Australia provides national advance care planning resources for individuals, families, health professional and service providers. Resources include a national advisory service, information resources, a legal forms hub and education modules.

- Telephone: 1300 208 582
- Website <www.advancecareplanning.org.au>

Australasian Lymphology Association

The Australasian Lymphology Association has a number of key resources to assist people in gaining an understanding of lymphoedema and the treatments available for the condition.

- Telephone: 1300 935 332
- Website <www.lymphoedema.org.au>

Australian Cancer Survivorship Centre

The Australian Cancer Survivorship Centre has developed information resources and events to help people move from initial treatment to post treatment and beyond, including those receiving maintenance treatments. While they do not provide clinical advice, they connect with a range of providers to enable improved care.

- Telephone: (03) 8559 6220
- Website <www.petermac.org/cancersurvivorship>

Australian Commission on Safety and Quality in Health Care

The Australian Commission on Safety and Quality in Health Care has developed a resource for patients and carers explaining the coordination of care that patients should receive from their health service during cancer treatment. The resource is called *What to expect when receiving medication for cancer care* <<https://www.safetyandquality.gov.au/publications-and-resources/resource-library/what-expect-when-receiving-medication-cancer-care>>.

Beyond Blue

Beyond Blue provides information about depression, anxiety and related disorders, as well as about available treatment and support services.

- Telephone: 1300 22 4636
- Website <www.beyondblue.org.au>

Breast Cancer Network Australia

Breast Cancer Network Australia is a consumer organisation providing specific information on breast cancer.

- Telephone: 1800 500 258
- Website <www.bcna.org.au>

Cancer Australia

Cancer Australia provides information for consumers, carers and their families including printed resources and video content.

- Website <www.canceraustralia.gov.au>

Cancer Council's Cancer Information and Support Service

Cancer Council 13 11 20 is a confidential telephone support service available to anyone affected by cancer. This service acts as a gateway to evidence-based documented, practical and emotional support available through Cancer Council services and other community organisations. Calls will be answered by a nurse or other oncology professional who can provide information relevant to a patient's or carer's situation. Health professionals can also access this service.

- Telephone: 13 11 20 – Monday to Friday, 9.00am to 5.00pm (some states have extended hours)
- Website <www.cancer.org.au/about-us/state-and-territory-councils/>

Cancer Council's Cancer Connect

Cancer Connect is a free and confidential telephone peer support service that connects someone who has cancer with a specially trained volunteer who has had a similar cancer experience.

A Connect volunteer can listen with understanding and share their experiences and ways of coping. They can provide practical information, emotional support and hope. Many people newly diagnosed with cancer find this one-to-one support very beneficial.

For more information on Cancer Connect call Cancer Council on 13 11 20.

Canteen

Canteen helps adolescents, young adults and parents to cope with cancer in their family. Canteen offers individual support services, peer support services and a youth cancer service, as well as books, resources and useful links.

- Telephone: 1800 835 932 to talk to a health professional about information and support for young people or 1800 226 833 for other enquiries
- Website <www.canteen.org.au/>

Clinical trial information

For a collection of clinical trials available in Australia see the following sources of information:

- Australian clinical trials <www.australianclinicaltrials.gov.au/>
- Australian New Zealand Clinical Trials Registry <www.anzctr.org.au/>
- ClinicalTrials.gov <www.clinicaltrials.gov/>

CanEAT pathway

A guide to optimal cancer nutrition for people with cancer, carers and health professionals.

- Website <<https://education.eviq.org.au/courses/supportive-care/malnutrition-in-cancer/>>
- Website <<https://patients.cancer.nsw.gov.au/coping-with-cancer/physical-wellbeing/eating-well/>>

Guides to best cancer care

The short guides help patients, carers and families understand the optimal cancer care that should be provided at each step. They include optimal timeframes within which tests or procedures should be completed, prompt lists to support patients to understand what might happen at each step of their cancer journey and to consider what questions to ask, and provide information to help patients and carers communicate with health professionals.

The guides are located on an interactive web portal, with downloadable PDFs available in multiple languages.

- Website <www.cancercareguides.org.au/>

Look Good, Feel Better

A free national community service program, run by the Cancer Patients Foundation, dedicated to teaching cancer patients how to manage the appearance-related side effects caused by treatment for any type of cancer.

- Telephone: 1800 650 960
- Website <<https://lgfb.org.au/>>

McGrath Foundation

The McGrath Foundation employs breast care nurses who help individuals and their families experiencing breast cancer by providing physical, psychological and emotional support.

- Telephone: (02) 8962 6100
- Website <<https://www.mcgrathfoundation.com.au/>>

Quitline

Quitline is a confidential, evidence-based telephone counselling service. Highly trained Quitline counsellors use behaviour change techniques and motivational interviewing over multiple calls to help people plan, make and sustain a quit attempt.

Quitline is a culturally inclusive service for all, and Aboriginal counsellors are also available. Health professionals can refer patients to Quitline online or via fax.

- Telephone: 13 7848
- Website <www.quit.org.au> or the relevant website in your state or territory.

For health providers

Australian Cancer Survivorship Centre

The Australian Cancer Survivorship Centre provides expertise in survivorship care, information, support and education. Its purpose is to support and enable optimal survivorship care.

- Telephone: (03) 8559 6220
- Website <www.petermac.org/cancersurvivorship>

Australian Commission on Safety and Quality in Health Care

The Australian Commission on Safety and Quality in Health Care has developed a guide for clinicians containing evidence-based strategies to support clinicians to understand and fulfil their responsibilities to cancer patients. This guide is particularly relevant to steps 3 to 6 of the optimal care pathway. The guide is titled *NSQHS Standards user guide for medication management in cancer care for clinicians* <<https://www.safetyandquality.gov.au/publications-and-resources/resource-library/nsqhs-standards-user-guide-medication-management-cancer-care-clinicians>>.

Cancer Australia

Information for health providers including guidelines, cancer learnings, cancer guides, reports, resources, videos, posters and pamphlets.

- Website <www.canceraustralia.gov.au>

Cancer Council Australia

Information on prevention, research, treatment and support provided by Australia's peak independent cancer authority.

- Website <www.cancer.org.au>

CanEAT pathway

A guide to optimal cancer nutrition for people with cancer, carers and health professionals.

- Website <<https://education.eviq.org.au/courses/supportive-care/malnutrition-in-cancer>>
- Website <<https://patients.cancer.nsw.gov.au/coping-with-cancer/physical-wellbeing/eating-well>>.

CounterPart

Peer support for women living with breast or gynaecological cancer. This support service offers high-quality evidence-based educational resources and a drop-in centre.

- Phone: 1300 781 500
- Website <<https://counterpart.org.au/>>

eviQ

A clinical information resource providing health professionals with current evidence-based, peer-maintained, best practice cancer treatment protocols and information relevant to the Australian clinical environment.

- Website <www.eviq.org.au>

National Health and Medical Research Council

Information on clinical practice guidelines, cancer prevention and treatment.

- Website <www.nhmrc.gov.au>

Glossary

advance care directive – voluntary person-led document that focus on an individual's values and preferences for future health and medical treatment decisions, preferred outcomes and care. They are completed and signed by a competent person. They are recognised by specific legislation (statutory) or common law (non-statutory). Advance care directives can also appoint the substitute decision-maker(s) who can make decisions about health or personal care on the individual's behalf if they are no longer able to make decisions themselves. Advance care directives focus on the future health care of a person, not on the management of his or her assets. They come into effect when an individual loses decision-making capacity.

advance care planning – the process of planning for future health and personal care, where the person's values, beliefs and preferences are made known so they can guide decision making at a future time when that person cannot make or communicate their decisions.

alternative therapies – treatments used in place of conventional medical treatment.

care coordinator – the health provider nominated by the multidisciplinary team to coordinate patient care. The care coordinator may change over time depending on the patient's stage in the care pathway and the location and care in which care is being delivered.

complementary therapies – supportive treatment used in conjunction with conventional medical treatment. These treatments may improve wellbeing and quality of life and help people deal with the side effects of cancer.

end-of-life care – includes physical, spiritual and psychosocial assessment, and care and treatment, delivered by health professionals and ancillary staff. It also includes support of families and carers and care of the patient's body after their death.

immunotherapy – a type of cancer treatment that helps the body's immune system to fight cancer. Immunotherapy can boost the immune system to work better against cancer or remove barriers to the immune system attacking the cancer.

indicator – a documentable or measurable piece of information regarding a recommendation in the optimal care pathway.

informed financial consent – the provision of cost information to patients, including notification of likely out-of-pocket expenses (gaps), by all relevant service providers, preferably in writing, before admission to hospital or treatment (Commonwealth Department of Health 2017).

lead clinician – the clinician who is nominated as being responsible for individual patient care. The lead clinician may change over time depending on the stage of the care pathway and where care is being provided.

metastatic disease – cancer that has spread from the part of the body where it started (the primary site) to other parts of the body.

multidisciplinary care – an integrated team approach to health care in which medical and allied health providers consider all relevant treatment options and collaboratively develop an individual treatment plan for each patient.

multidisciplinary team – comprises the core disciplines that are integral to providing good care. The team is flexible in approach, reflects the patient's clinical and psychosocial needs and has processes to facilitate good communication.

multidisciplinary team meeting – a meeting of health professionals from one or more clinical disciplines who together make decisions about recommended treatment of patients.

optimal care pathway – the key principles and practices required at each stage of the care pathway to guide the delivery of consistent, safe, high-quality and evidence-based care for all people affected by cancer.

performance status – an objective measure of how well a patient can carry out activities of daily life.

primary care health professional – in most cases this is a general practitioner but may also include general practice nurses, community nurses, nurse practitioners, allied health professionals, midwives, pharmacists, dentists and Aboriginal health workers.

spiritual care – the aspect of humanity that refers to the way individuals seek and express meaning and purpose and the way they experience their connectedness to the moment, to self, to others, to nature, and to the significant or sacred.

substitute decision-maker – a person permitted under the law to make decisions on behalf of someone who does not have competence or capacity.

supportive care – care and support that aims to improve the quality of life of people living with cancer, cancer survivors and their family and carers and particular forms of care that supplement clinical treatment modalities.

survivorship – an individual is considered a cancer survivor from the time of diagnosis, and throughout their life; the term includes individuals receiving initial or maintenance treatment, in recovery or in the post-treatment phase.

survivorship care plan – a formal, written document that provides details of a person's cancer diagnosis and treatment, potential late and long-term effects arising from the cancer and its treatment, recommended follow-up, surveillance, and strategies to remain well.

targeted therapy – a medicine that blocks the growth and spread of cancer by interfering with specific molecules.
